14. ABSTRACT

This pipe stress analysis evaluated the pipelines according to ASME B31.3, Process Piping and AISC 360-16, Structural Pipe Supports. The purpose of this analysis was to evaluate the areas of concern identified by an independent assessment of the lower access tunnel piping system. The results would provide numerical data and a basis for repair recommendations for safe defueling of the Red Hill facility.

EXECUTIVE SUMMARY

(b) (3) (A) is a subconsultant to APTIM Federal Services. APTIM is under contract to Naval Facilities Engineering and Expeditionary Warfare Center (NAVFAC EWC), Contract N39430-20-D-2225, Task Order (TO) N3943021F4207 to perform emergent repairs at Red Hill Underground Fuel Storage Complex, Joint Base Pearl Harbor-Hickam (JBPHH), Hawaii. This pipe stress analysis evaluated the pipelines according to ASME B31.3, Process Piping and AISC 360-16, Structural Pipe Supports. The purpose of this analysis was to evaluate the areas of concern identified by an independent assessment of the lower access tunnel piping system. The results would provide numerical data and a basis for repair recommendations for safe defueling of the Red Hill facility.

Approach

The Pipe Stress Analysis considered the effects of gravity, sustained pressure, and seismic loads on the three major pipelines and tank laterals in the lower access tunnel. The objective was to identify conditions of high stress and determine if the piping system would be safe for defueling under intended operating conditions. Two pressure cases were considered in the stress analysis: an operating case of 85 psi to drain the tanks (based on the tank head pressure of a full tank), and a maximum allowable operating pressure (MAOP) of 285 psi for a Class 150 piping system. The piping system was modeled from 3D scans of the existing facility and updated to reflect ongoing repairs and modifications to the piping. Pipe support loads generated by the stress analysis at operating pressure conditions were then used to evaluate the potential failure of selected supports, PS-46 through PS-48 and PS-78 through PS-92.

Findings and Recommendations

The results of the stress analysis revealed that piping stresses can exceed code allowable limits at various locations along the three major pipelines. With a pressure load case of 85 psi, the system is code compliant in hoop stress but fails in sustained stress and occasional seismic stress unless some modifications are made. With a pressure load case of 285 psi (a full Class 150 MAOP), the system fails code requirements in the hoop, sustained, and occasional seismic stress. The effects of pressure surges on piping stress and support loads were not evaluated because they cannot be mitigated by structural or piping modifications and must be prevented by operational procedures.

The repairs recommended herein will allow the system to operate within code-allowable stress limits at operating pressures up to 85 psi, which will be sufficient to gravity-drain the tanks. Operating the piping systems at pressures above 85 psi is not recommended. Recommended repairs include shimming existing supports that do not contact the pipe, adding two vertical supports (one on the -inch pipeline tee at Tanks 1 and 2 and one on the -inch pipeline tee at Tanks 11 and 12), and adding guides to existing vertical supports adjacent to the tank lateral piping and on select tank lateral piping. With these modifications, the system can be brought into code compliance for operations at 85 psi.

Minor deficiencies were identified in a total of 13 of the 18 pipe supports evaluated. In most cases, the failure mode was determined to be either the shear breakout of the anchor rods from the concrete piers or compression overloading of the diagonal bracing. These supports only require modifications in select areas and can be upgraded without replacement or movement of existing members. The repairs consist primarily of providing additional bracing of the pipe support columns. Additionally, two supports will require an added column and base plate positioned underneath the -inch diameter pipe.

APPENDIX

RED HILL PIPELINE LOWER ACCESS TUNNEL
STRESS ANALYSIS AND STRUCTURAL EVALUATION REPORT

1.0 INTRODUCTION

(b) (3) (A) is a subconsultant to APTIM Federal Services. APTIM is under contract to Naval Facilities Engineering and Expeditionary Warfare Center (NAVFAC EWC), Contract N39430-20-D-2225, Task Order (TO) N3943021F4207 to perform emergent repairs at Red Hill Underground Fuel Storage Complex, Joint Base Pearl Harbor-Hickam (JBPHH), Hawaii.

The Scope of Work (SOW) for TO F4207 was originally outlined in the 6-part RFP X018 dated 8 June 2021. This SOW was awarded on 14 July 2021. The purpose of this project is to repair fuel piping and transfer pipelines at and between the Red Hill Bulk Fuel Storage Facility tank farm and Joint Base Harbor Hickam. Repairs in the base award include providing temporary piping in the cross tunnels of out-of-service tanks to provide lateral support to the tunnel piping and repairing piping and supports in the lower access tunnel. Modification 001 to add hydrostatic testing and pipe stand repair was issued on 4 March 2022. The SOW for Modification 002 was issued on 26 April 2022. Notice to Proceed was issued on 20 May 2022. Modification 002 SOW includes pipe stress analysis, pipe support structural analysis, development of a concept to relieve low-pressure conditions in JP-5 and F-24 pipelines and a concept to defuel F-76 utilizing (b -inch F-24 or (b -inch JP-5 pipelines. This document only addresses the Modification 002 SOW related to pipe stress analysis and pipe support structural analysis. The relief of low-pressure conditions and F-76 defuel was submitted in June 2022 under a separate cover.

Objective

The pipe stress analysis was performed on the fuel piping system from the bulkhead beyond pipe support 106 (PS-106) to the top of the lower access tunnel (PS-1). The analysis will identify conditions of high stress and determine whether the piping system and pipe couplings are safe for defueling under intended operating conditions. Intended operating conditions for defueling exclude consideration of fuel thermal effects. Fuel in the Red Hill facility is at a constant temperature in the tanks and piping because they are buried or in tunnels and do not see any thermal gain from the sun. It is not intended that new fuel would be received, therefore no low-temperature fuel from colder locations would be introduced to the piping system. As fuel receipts will not be considered, no evaluation of pumping scenarios will be included, only tank pressure head, maximum allowable operating pressures, and seismic loads will be considered. The effects of pressure surges on piping stress and support loads were not evaluated. Pressure surges can create damaging impulses that cannot be mitigated by structural or piping modifications and must be prevented by operational procedures or mitigated by pressure control and relief systems. Specific pipe supports (PS-46 to PS-48 and PS-79 to PS-92) were evaluated for seismic load adequacy.

Existing Facility

The Red Hill complex consists of 20 mined fuel tanks that were completed construction circa 1942. The Red Hill tanks are the primary bulk storage tanks for the three major products handled at Pearl Harbor (F-24, JP-5, and F-76). Three main transfer lines in the lower access tunnel carry fuel to and from Red Hill (a (b -inch F-76 line, an (b -inch JP-5 line, and a (b -inch F-24 line). The fuel lines are approximately (miles in length and are located in a tunnel from the Red Hill Tank Gallery to the Underground Pumphouse, Facility 59 (UGPH59). Tanks 1-16 have two common fill and issue lines that branch off the three main transfer lines. Tanks 17-20 have one common fill and issue line connected only to the (b -inch JP-5 line.

Only the piping in the tank area, from the bulkhead beyond PS-106 to the top of the lower access tunnel (PS-1) was evaluated under this project. The (-mile pipeline to UGPH59 was not identified as a concern and was not assessed.

At the time of this report, Tanks 1 and 19 have been out of service and drained of fuel for several years. Tanks 13-14 and 17-18 are empty and under construction for clean, inspect, and repair (CIR) contracts. Repairs included modifying piping in the lower access tunnel. These repairs have been included in the stress analysis. Tanks 2 through 12, 15, 16, and 20 are presently filled with product.

Site Investigation

Site investigations for Modification 002 started on 16 May 2022 and were completed in mid-July 2022. The pipe in the lower access tunnel and all overhead supports were scanned using a 3D scanner. In addition to referencing existing design drawings and other documents, (b) conducted numerous walkdowns to document any conditions which would impact this analysis. The design basis for modeling the system considered the current ongoing work as completed construction, necessary for resuming operations and defueling the facility.

2.0 STRESS ANALYSIS ENGINEERING ASSESSMENT

This stress analysis calculation was prepared to evaluate the existing conditions of the Red Hill lower access tunnel piping. The objective was to evaluate the piping under the effects of gravity, sustained pressure, and seismic loads. It also evaluated loads at select pipe support to facilitate the structural evaluation. See Section 3.0 Pipe Support Structural Analysis for further discussion.

Calculation Method and Analysis

The pipe stress calculations were performed using BENTLEY® AutoPIPE (CONNECT Edition, Version 12.08), Static and Dynamic Analysis software. The program is a finite element analysis-based engineering application used for the calculation of piping stresses, deflections, and forces under static loading conditions.

A three-dimensional (3D) computer model was created based on the current configuration of the piping which was documented through 3D scans. At the time of this report, Tanks 13-14 and 17-18 were empty and under construction. Modeling for these areas was based on the CIR tank modification drawings. Piping in the tunnels was also modeled according to the ongoing FY21 Emergent Pipeline Repair drawings for Tanks 1, 18-20, and the tee at Tank 5. This ongoing work was assumed to be complete for the purpose of this analysis. An overview of the piping configuration and geometry is shown in Figure 1. The limits of the model were bounded between the end of the tunnel, near Tanks 19 and 20, and an anchoring bulkhead near PS-106. Tank lateral piping connected to each of the tanks was modeled as anchors at the tank wall.

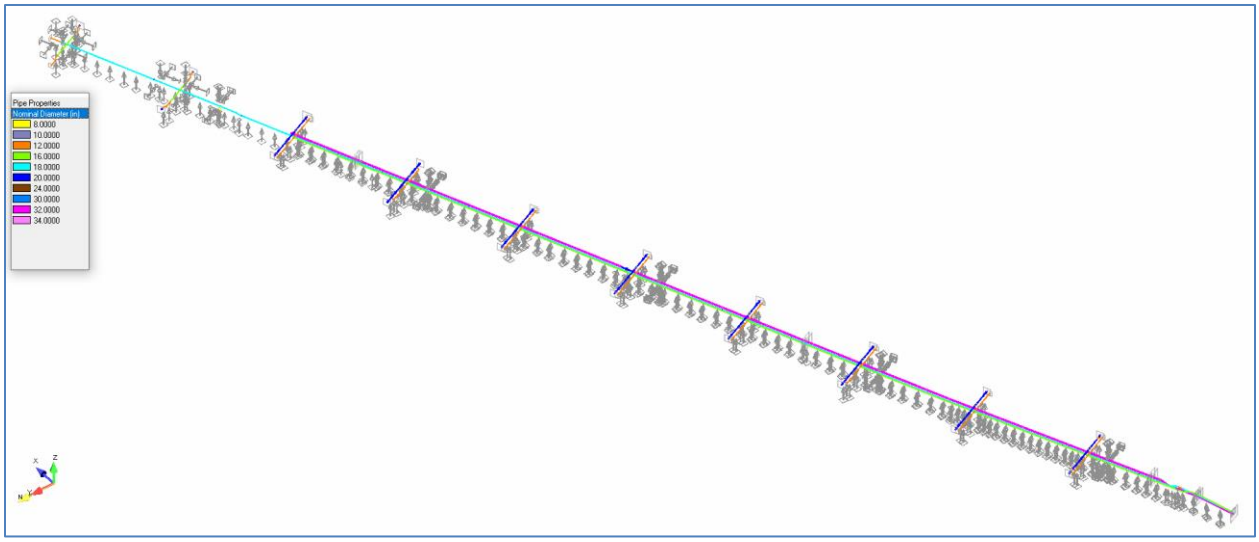

Figure 1: Lower Access Tunnel Pipeline Model Overview

Load Cases

The following load cases were applied to the model (see Appendix B for input report):

- **Gravity (G)** loads of the pipe and contents, except those tanks "empty" or out of service, up to the spec blind.
- **Pressure (P1, P2)** loads P1 for an operating case of 85 psi and P2 for maximum allowable operating pressure (MAOP) of 285 psi, Class 150 flange rating.
- **Temperature (T1, T2)** loads modeled as an average tunnel temperature of 65°F.
- **Static seismic (E1, E2, E3)** loads from UFC 3-301-01 for Pearl Harbor, HI as calculated from ASCE 7-10. E1 modeled acceleration in the north, east, and vertical directions. E2 modeled acceleration in the east and vertical directions, and E3 modeled acceleration in the north and vertical directions.

Assumptions

For a full summary of model inputs, see Appendix B. The following assumptions were made in creating the model:

- All piping greater than (b inch nominal pipe size is either standard wall thickness or Schedule 10. This was spot-checked with ultrasonic measurements during the field site investigation.
- The system is mostly constructed as ANSI Class 150, with a nominal MAOP of 285 psi. A few select valves and flanges are ANSI Class 300.
- The temperature of piping and fuel remains constant year-round. No new fuel (of a different temperature) is added to the system.
- Pipe supports modeled as vertical supports. Guide supports were modeled at wall penetrations and some new pipe supports at Tanks 17-20.
- Branch connections are a mixture of forged tees and unreinforced stub-on connections (with a higher stress intensification factor (SIF)).

- Dresser couplings (Style 38) in tank laterals of the even-numbered tanks were modeled as expansion joints with a spring stiffness of zero. The couplings are fit with Type 440 joint harnesses modeled as tie-rod supports, and welded lugs on the pipe modeled as rigid beams.
- Butt welded bell and socket piping ends were approximated with back-to-back non-standard reducers.

Summary of Findings

The load cases were applied to the model and stress combinations were evaluated per ASME B31.3, Process Piping.

- Hoop stress is circumferential stress due to internal pressure (P1, P2).
- Sustained stress is gravity (G) + pressure, internal (P1, P2).
- Occasional stress is determined by applicable combinations, in this case, sustained (G + P1, P2) + earthquake, seismic (E1, E2, E3). As the Red Hill piping is in tunnels, no wind or snow loads were applied. And there was no potential for thermal differential.

The results are presented as a ratio between calculated stress and allowable stress values. Any ratio over 1.00 is not allowed. **Analysis of the B31.3 code combinations revealed that in some locations, the piping stresses were not within the allowable range.** Figures shown below represent only the operating case of P1 (85 psi). Over-stressed areas, any ratio over 1.00, show as red.

Hoop Stress

The maximum allowable hoop stress is 20 kips per square inch (ksi). For operating pressure, P1, the maximum calculated stress ratio is 0.44. This occurred in the (b -inch pipeline near PS-101, at the mitered bends approaching the double block and bleed (DB&B) valve (see Figure 2). In the operating pressure case, P1, all hoop stress ratios were within code allowable limits. For Class 150 MAOP, P2, the maximum calculated stress ratio is 1.47. This occurred near PS-101 in the (b -inch pipeline at a mitered bend. All three pipelines in this area with mitered bends exceeded code allowable limits. All other points in the model were within code allowable limits for hoop stress in the P2 case.

Maximum Hoop Stress Results		
Load Case	**P1**	**P2**
Stress Ratio	0.44	**1.47**

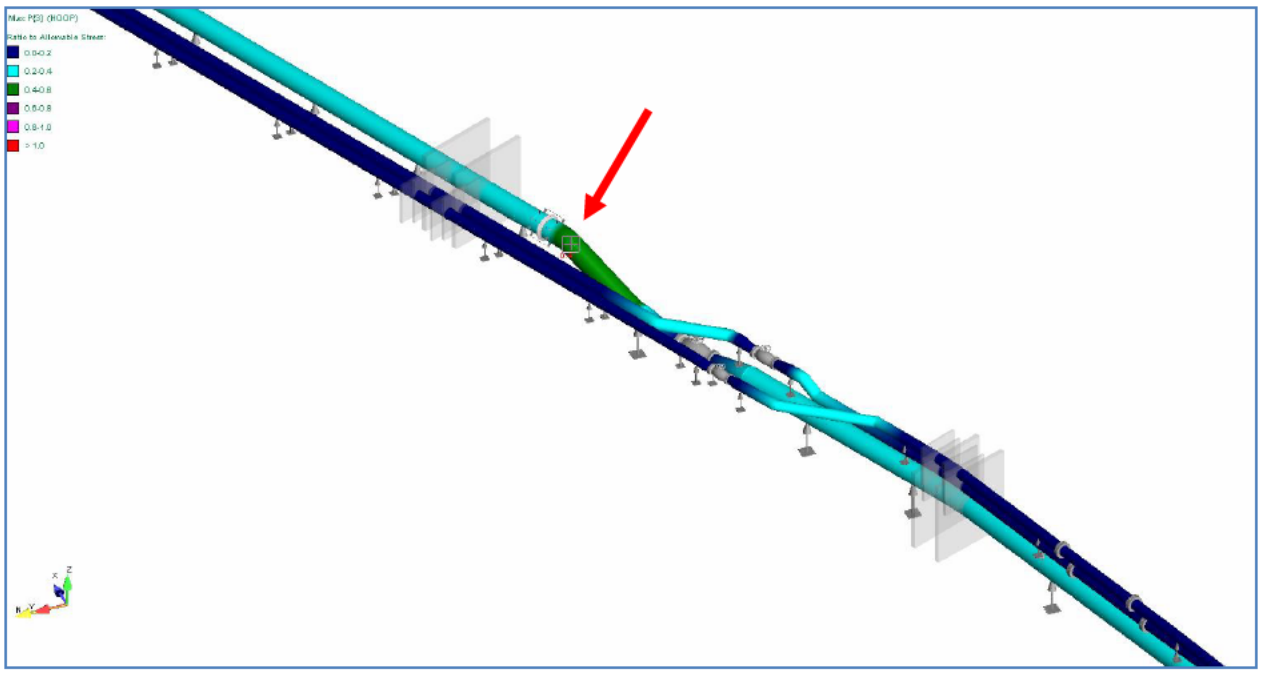

Figure 2: Maximum Hoop Code Stress of P1 load case (end of tunnel piping)

Sustained Stress

Sustained stress, the effects of gravity combined with pressure, has a maximum allowable stress of 20 ksi. In the operating case, P1, the maximum calculated stress ratio is 1.06. This is located at the Tank 1 and 2 (b -inch tee to the(b) -inch lateral (see Figure 3). For the operating pressure P1, all other pipeline stresses were within code allowable limits. In the Class 150 MAOP case, P2, the maximum calculated stress ratio was also at Tank 1 and 2 (b -inch tee to (b -inch lateral. All other points in the model were within code allowable limits for the Class 150 MAOP case.

Maximum Sustained Stress Results		
Load Case	**P1**	**P2**
Stress Ratio	**1.06**	**1.07**

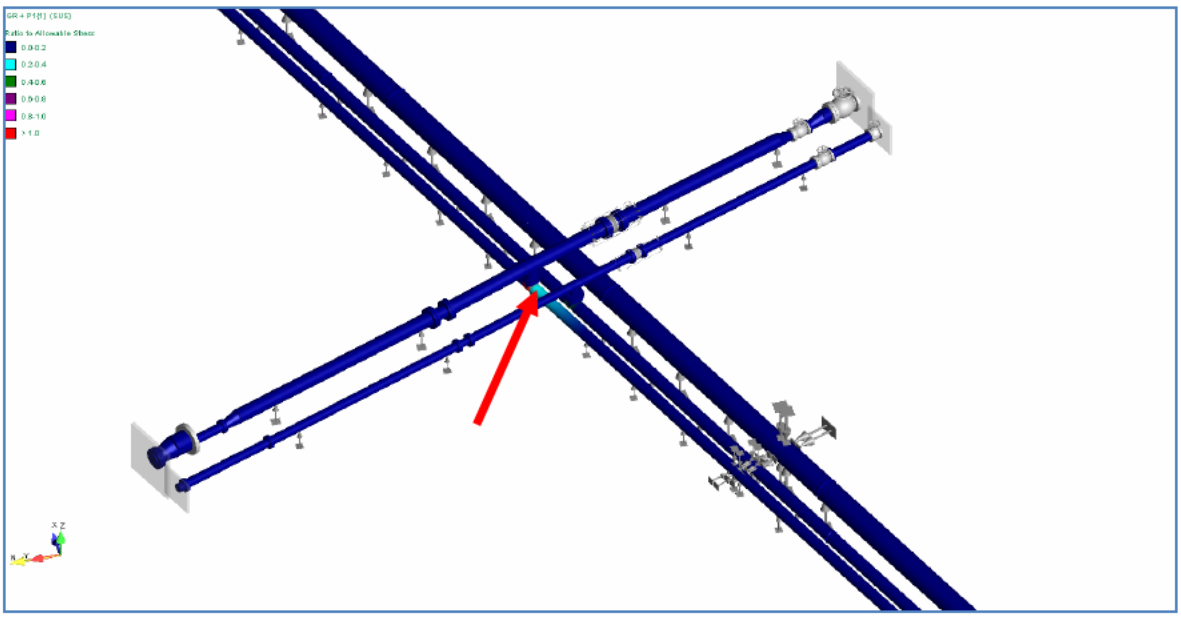

Figure 3: Maximum Sustained Code Stress of P1 load case (Tank 1 on the left, Tank 2 on the right)

Occasional Stress (Seismic)

Occasional stress, in this scenario a design level seismic event, has a maximum allowable stress of 26.6 ksi. In the operating case (P1) of sustained plus seismic loads, the maximum calculated stress ratio is 5.32. This occurred at the tee near Tank 1 and 2 of the (b -inch pipeline to the (b -inch lateral (see Figure 4). Pipeline stresses at most all the tees between tank laterals and tunnel pipelines exceeded code allowable limits. Tees at Tanks 17-20, the (b -inch tee of Tanks 5, 6, 15, and 16 and all other piping in the model were within code allowable limits of the occasional seismic load. In the Class 150 MAOP case, P2 + E2, the maximum calculated stress ratio was 5.30, also at Tank 1 and 2, 16-inch tee to 20-inch lateral.

Maximum Occasional Stress Results		
Load Case	**P1+E3**	**P2+E2**
Stress Ratio	**5.32**	**5.30**

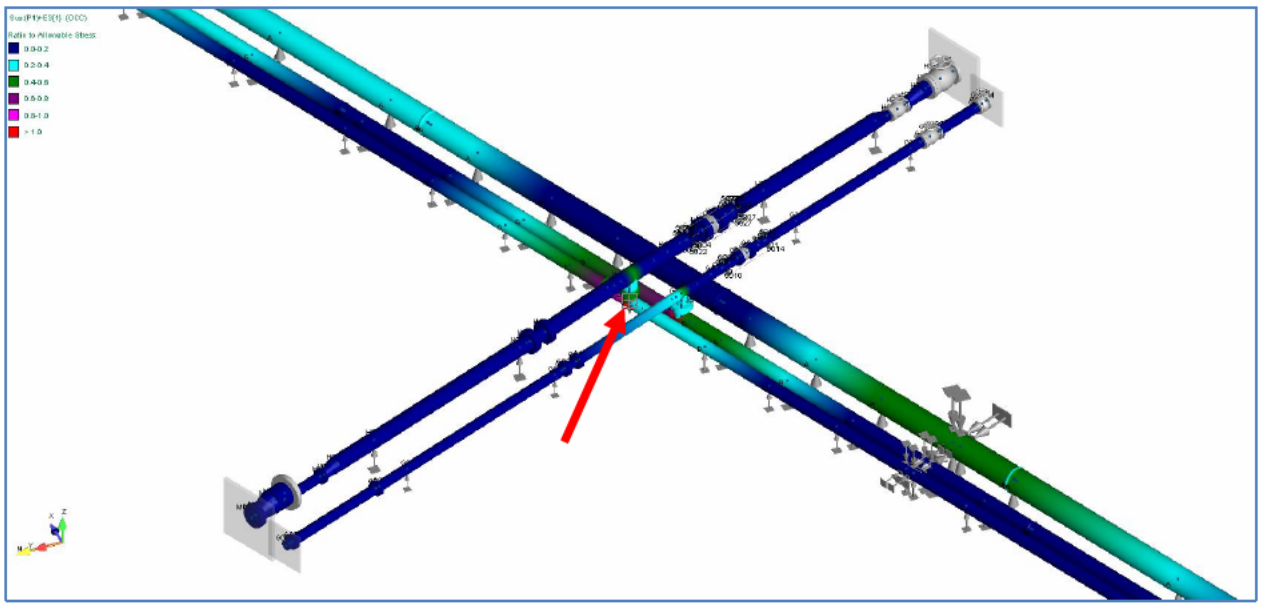

Figure 4: Maximum Occasional Code Stress Ratio of P1 load case (Tank 1 on the left, Tank 2 on the right)

For more reporting on the piping stress and loads, see the result screenshots included in Appendix A and a model output summary of maximum stresses in Appendix C.

Recommendations

To bring the lower access tunnel piping system into compliance with allowable code stress limits, modifications will need to be made to the existing piping system. **The recommended modifications will allow the system to operate at pressures up to 85 psi, which will be sufficient to gravity-drain the tanks.** The recommended changes will not be sufficient to maintain compliance with code stress limits at pressures above 85 psi, therefore operating the piping systems at pressures above 85 psi is not recommended.

At a full Class 150 rating (285 psi MAOP), the three pipelines failed in hoop stress at the mitered bends near PS-101. It is recommended that the facility adopt a new maximum allowable operating pressure of 193 psi just to maintain a code-compliant hoop stress ratio in all three of the pipelines. An intended operating pressure of 85 psi (gravity draining the existing tanks) is well within this pressure limit.

Mandatory Repairs

Mandatory repairs listed below are required for bringing the system into code compliance with a maximum intended operating pressure of 85 psi. The recommendations included are of a preliminary nature and have not been verified through structural design but focus on mitigating issues of piping stress.

1. At seven pipe support locations, there is no contact between the pipe and the vertical support. It is recommended to provide shims to bring the support in contact with the pipe.

	Pipe Support
(b -inch Pipeline	PS-46, PS-47, PS-73, PS-74
(b -inch Pipeline	PS-11, PS-13, PS-16

2. In the case of sustained stress (P1), a vertical support must be added below the tee at the (b -inch pipeline to the (b -inch lateral at the Tanks 1 and 2 corridors (see red highlight in Figure 5). Adding a vertical support under the (b -inch tee reduces the code stress to 0.11 The new maximum code stress in sustained loading is 0.49 at the (b -inch tee near Tanks 15 and 16.

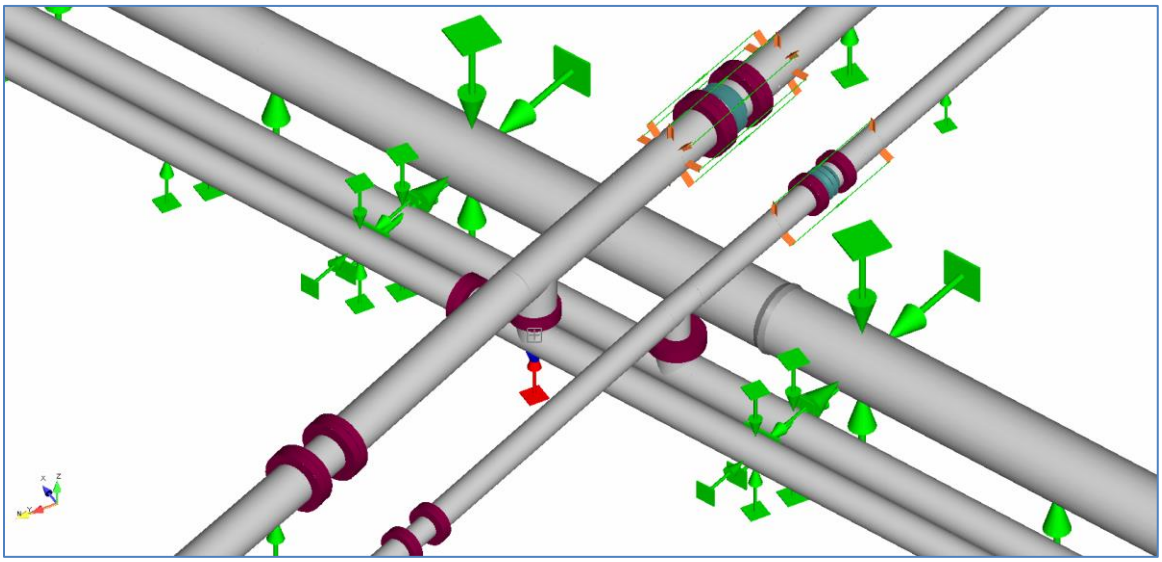

Figure 5: Vertical Support on the 16-inch pipeline at Tanks 1 and 2

To address the issues present in a design-level seismic event, a number of modifications must be made to the piping.

3. Add tight guide supports (zero gaps) to the vertical supports adjacent to the tank laterals at each corridor (see red highlights in Figure 6).

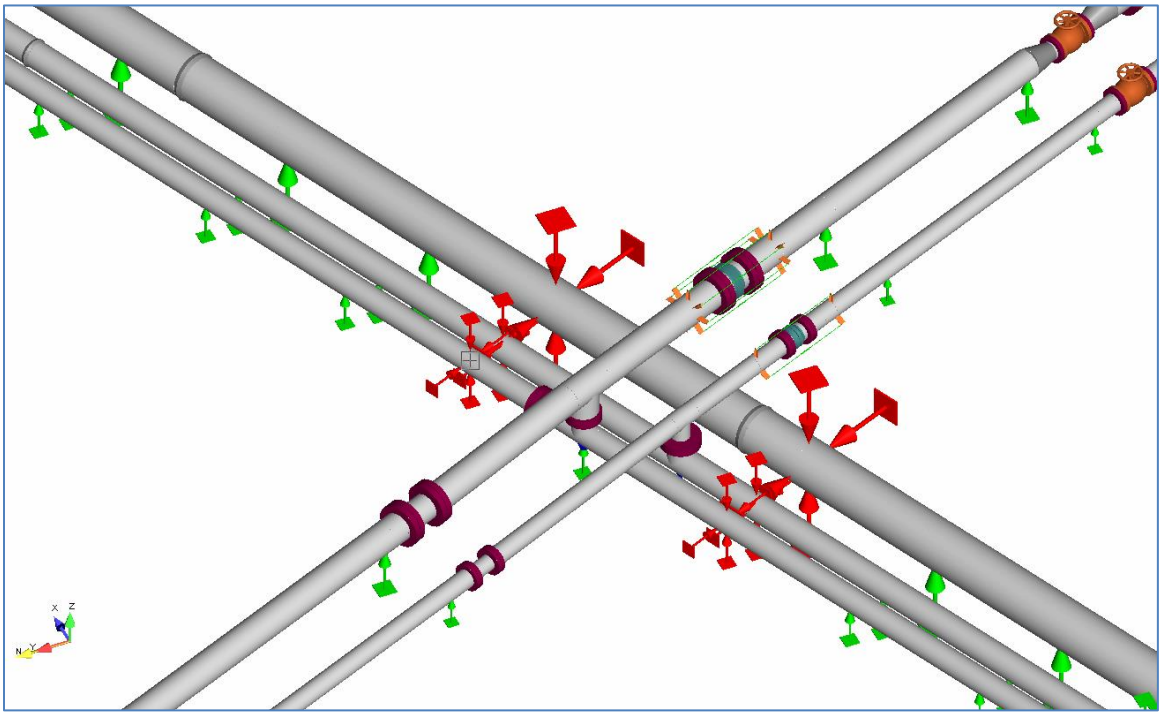

Figure 6: Guide Supports PS-92, PS-93 adjacent to Tank Laterals

4. Add tight guide supports at each first pipe support of the tank laterals at Tanks 3-8, 11-12, and 15-16 (see red highlights in Figure 7).

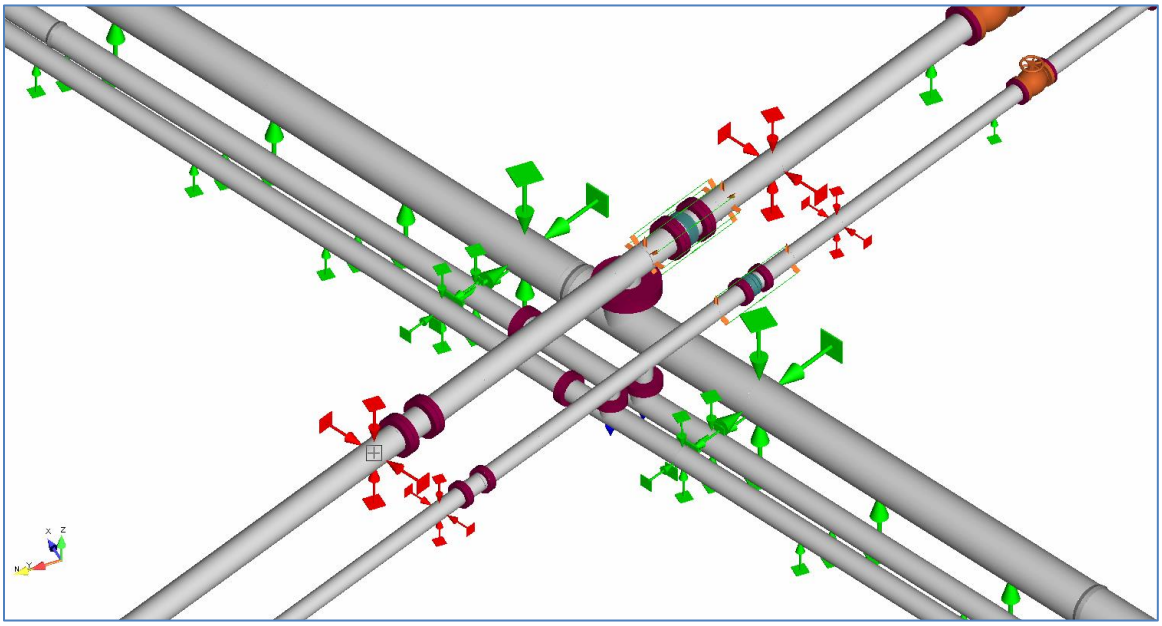

Figure 7: Guide Supports at tank laterals PS-1 of Tank 3 and Tank 4

5. Add a tight guide support to PS-47 on the (b -inch pipeline (see red highlight in Figure 8). This reduces code stress due to seismic to 1.00.

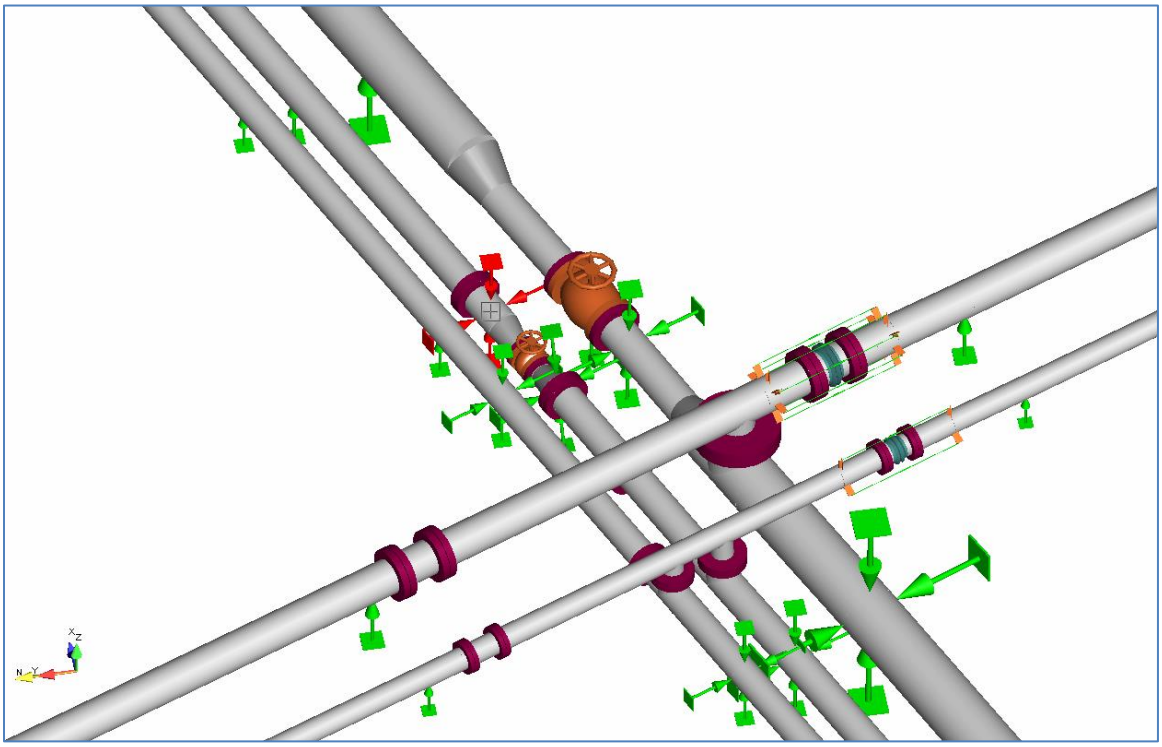

Figure 8: Guide Support at PS-47

6. To further reduce code stress, add a vertical support under the (b -inch to (b -inch tee at Tanks 11 and 12 (see red highlight in Figure 9). This reduces code stresses due to seismic to 0.95.

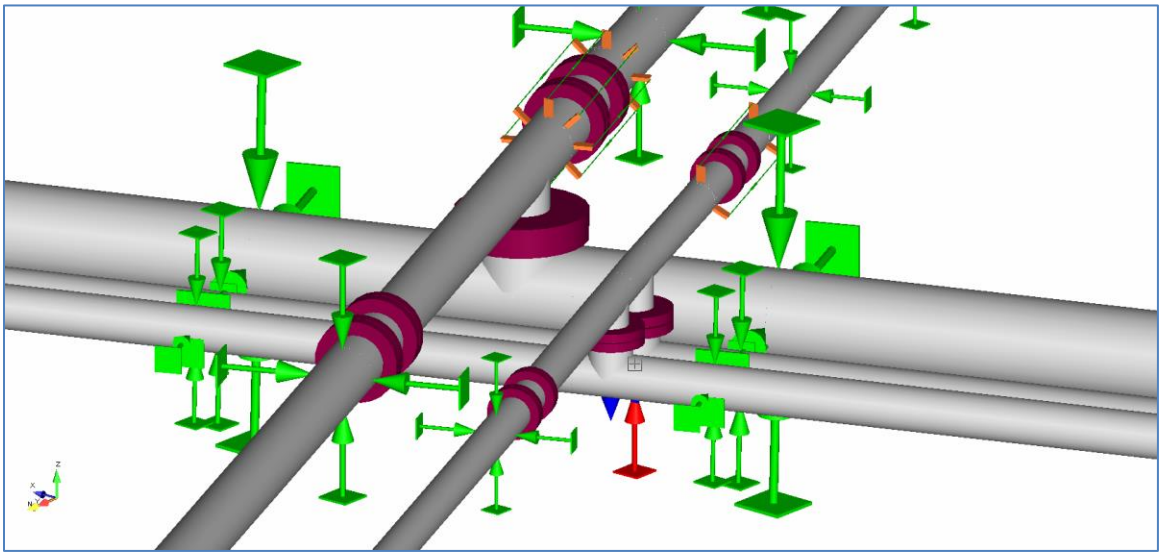

Figure 9: Vertical Support on the 18-inch pipeline at Tanks 11 and 12

For a summary report of the piping stress and loads with the proposed preliminary repairs, see the result screenshots included in Appendix A and a model output summary of maximum stresses in Appendix D.

Alternative Repairs

It is understood that dresser couplings are used in the tank laterals on the even tanks due to the potential for receiving cold fuel into the system. Since the facility will not be resupplied with fuel, the dresser couplings could be removed from the system.

7. Alternative to providing a vertical support (recommendation 6) under the (b -inch to (b -inch tee at Tank 11 and 12, removing the dresser couplings of Tank 12 reduces the occasional code stress to 0.91. This code stress considers recommendations 1-5 in addition to recommendation 7.

As determined by this analysis, the existing system of piping at Red Hill is not within allowable limits of ASME B31.3 for sustained stress and occasional stress. Following subsequent design and repair, the system could be brought into code compliance for operating pressures up to 85 psi. Though the hoop stress at PS-101 is within code limits up to 193 psi, it is recommended that the facility not exceed the design case of defueling the facility with a maximum tank head pressure of 85 psi.

3.0 PIPE SUPPORT STRUCTURAL ANALYSIS

The SOW included an evaluation of 18 pipe supports within the Red Hill lower access tunnel. These pipe supports have been designated as PS-78 through PS-92 and PS-46 through PS-48. The evaluation included the combined effects of the gravity, pressure, and seismic loads that were generated as outputs from the main pipe stress analysis. The results were based on an operating pressure of 85 psi. The structural calculations were performed using RISA 3D to analyze the support structures and Hilti PROFIS to analyze the anchor rod connections.

Pipe Support Description

As-built drawings of the supports were available for review. A site visit was performed to verify dimensions and member sizes. In general, the pipe supports were constructed as H-shaped frames using wide flange (W-section) steel sections. For PS-78 through PS-92, the horizontal beam was supported by a steel column on one side while the other end was embedded in the gunite lining of the tunnel wall. For PS-46 through PS-48, the horizontal beam was supported by a steel column at each end. PS-46 was embedded in the gunite lining as well, and PS-48 had a central column, totaling three columns for this pipe support. The bracing on the column side (in the direction of the pipe) was mixed; some supports had angle bracing on both sides, some had angle bracing on one side, and some were unsupported by any longitudinal bracing. All bracing was constructed from structural steel angles (L2-1/2 x 2-1/2 x 1/4 in most cases). Figure 10 shows a typical pipe support braced on both sides with diagonal angle bracing. The baseplates were a mix of 10-inch and 12-inch square plates, 3/4 thick, and attached to the concrete foundation with two anchor rods. The anchor rods are oriented in the longitudinal direction of the pipe. This allows for the support to be modeled as a fixed base with one rod in tension and the other in compression. However, in the transverse direction, the support is considered pinned. Although the as-built construction of the foundations could not be verified for each column base, some historical drawings have shown that the foundations are 12-inch square concrete pedestals.

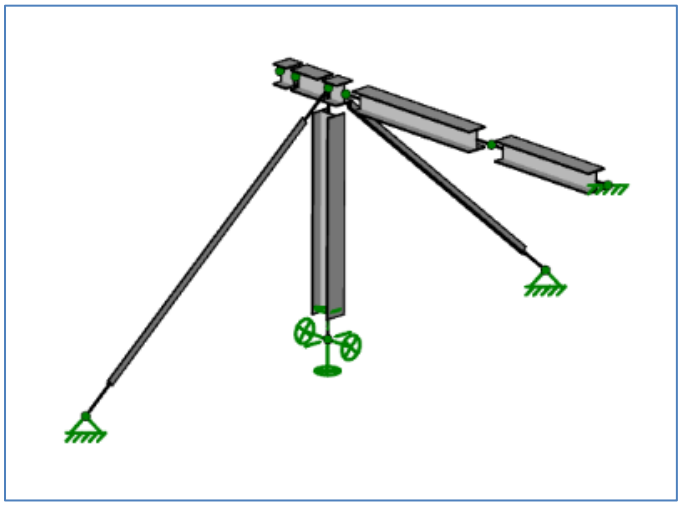

Figure 10: Typical Dual-Braced Pipe Support

Rather than create 18 models to address the minor differences in construction, simplifications were made to reduce the number of representative models to six. Model PS-80 represented PS-80, PS-81, PS-83, PS-84, PS-86, PS-88, PS-89, PS-90 and PS-92. Model PS-91 represented PS-79, PS-82, PS-85, PS-87 and PS-91. PS-46, PS-47, PS-48, and PS-78 were each modeled due to uniqueness in either geometry or loads.

Calculation Method and Analysis

Resultant loads from the pipe stress analysis were generated for each local direction of the pipe run – longitudinal to the pipe, transverse to the pipe, and vertical. There were five total load combinations provided – gravity load, pressure load at 85 psi, and three seismic load cases. As part of the structural analysis, pressure loading was interpreted as a dead load and combined with gravity. This resultant dead load combination was paired with the worst seismic load case in each direction. Out of the groupings listed in the pipe support description, the worst combinations from this process were identified and applied to the associated representative pipe support modeled in RISA 3D. Utilization ratios from AISC 360-16 Chapter H were generated for each member to determine which portions of the pipe supports are prone to failure. These ratios combine shear and moment utilization to create a realistic metric to assess failure. A ratio equal to or in excess of 1.0 indicates that the member experiences failure in one or more failure modes and must be modified before the support can be loaded.

From the RISA analysis, loads and moments were calculated at the baseplate of each representative support. The baseplates and anchorage were modeled in Hilti PROFIS based on site data and the RISA output. An assumption has been made to neglect the specific requirements of ACI 318-14 Chapter 17 *Anchoring to Concrete*. Substantial code changes have been made with respect to the behavior of concrete anchors since the construction of Red Hill. The specific code requirements for the failure of a ductile element over the failure of a brittle element have been set aside. The failure assessment has been limited to whether or not a pipe support would sustain the applied loads without failure of any element. Combined, these models were used to identify existing deficiencies in the pipe supports.

Summary of Findings

The analysis of the pipe support models under consideration revealed minor deficiencies in select areas. Generally, the W-section frames themselves pose no concerns, but the baseplates and bracing of certain pipe supports warrant modification to adequately resist the design loading. For the wire models below, the numbers represent the utilization ratios mentioned above.

Deficiency 1: It was found that for all pipes that only have bracing on one side (See Figure 11), this brace will pass within 5% of failure under design loading. Since seismic loads are variable, this is not ideal as any deviations above the design seismic event will likely result in the buckling or tensile yielding of these elements. If this were to happen, although the frames would adequately handle the new loads without failure, the base anchorage would fail and result in overturning of these pipe supports.

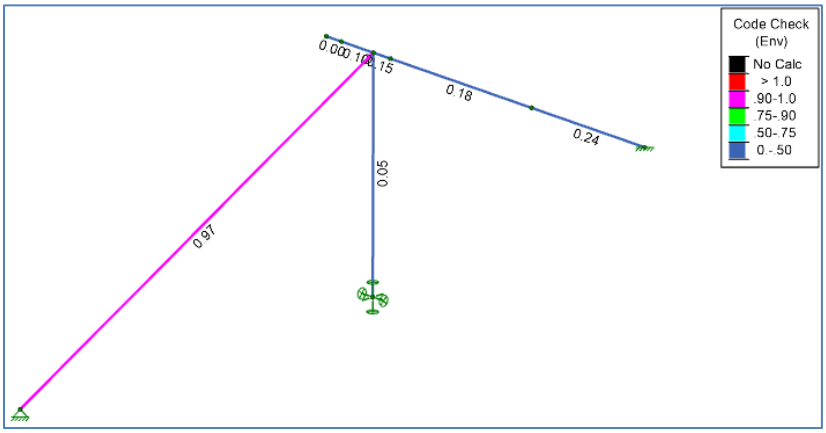

Figure 11: Supports Braced on One Side

Deficiency 2: There are two supports that are entirely unbraced. It was determined that, although there are no concerns with the members that the frame is comprised of, the lack of longitudinal bracing overloads the baseplate anchorage of these supports. The anchors and pier-style foundation underneath the supports will not be able to adequately resist the design load if the support were modeled as a cantilevered column. PS-78 is unbraced on the column side but embedded in the gunite wall on the other side, and PS-48 is unbraced on both sides of the support beam. Figure 12 and Figure 13 show PS-78 and PS-48 in their current conditions, respectively.

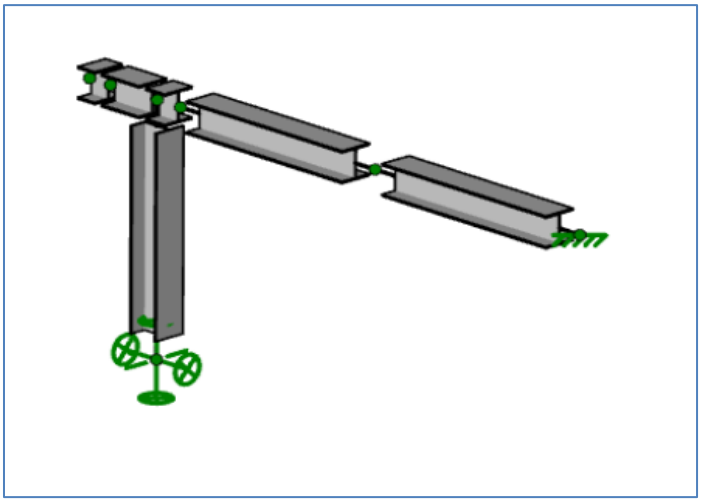

Figure 12: Existing PS-78

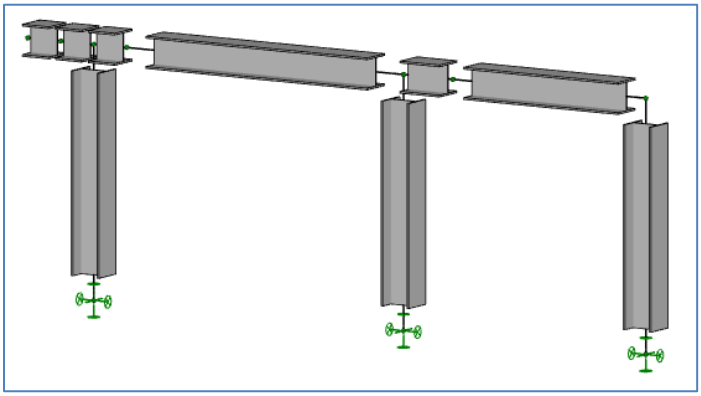

Figure 13: Existing PS-48

Deficiency 3: There are two concerns with PS-47 (See Figure 14). First, the support was severed in the middle of the beam to allow for the installation of a double block and bleed valve. This valve has been seated on a standalone support. This standalone support, from now on referred to as PS-47a, is comprised of a 6-inch standard vertical pipe stanchion. The stanchion is welded to a baseplate that is anchored by 4 anchor rods. Under design loading, PS-47a will fail at the anchor attachment between the baseplate and foundation. Modeling the support as a cantilever column applies a significant bending moment on the base. Second, the smaller portion of PS-47, (the side further from the wall), is laterally unsupported and requires some form of bracing to withstand any transverse loading conditions. The portion that is closer to the wall is supported via a W-section horizontal brace connecting it to PS-48. None of the pipes under consideration bear on top of this section. The application of any incident loads to this portion is outside the scope of this report.

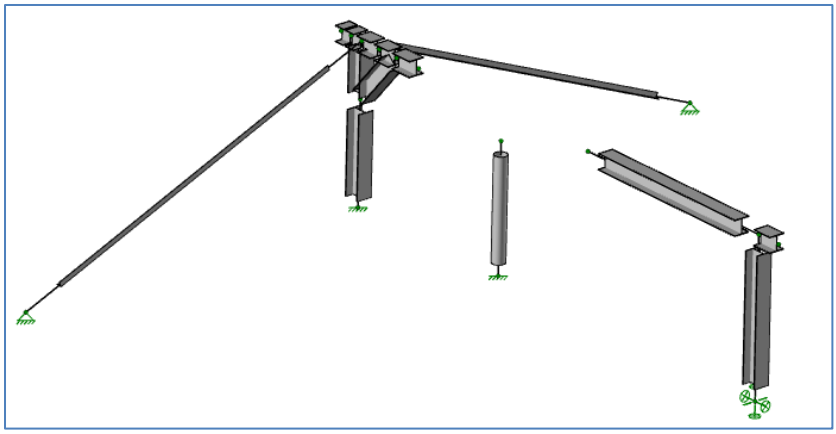

Figure 14: Existing PS-47

Deficiency 4: It was found that the anchorage of the baseplates is overloaded for the columns of PS-46. Although this support is fixed to the gunite wall and braced on either side of the outside column, PS-46 has a vertical downward load of over 10,000 pounds applied in the center of the beam. This load is significantly higher than any of the other vertical loads present from the pipe stress analysis. As the beam deflects downward in the center, it induces outward rotation at the tops of the columns, which causes them to bow outward from the center of the beam. This mechanism transfers shear forces to the baseplates as if they were unbraced, except the shear forces are perpendicular to the pipe instead of parallel to the pipe. This pipe support received much larger gravity loads than the rest of the supports, which is why failure in this way is unique to PS-46. The model of PS-46 in its current condition can be seen below (Figure 15).

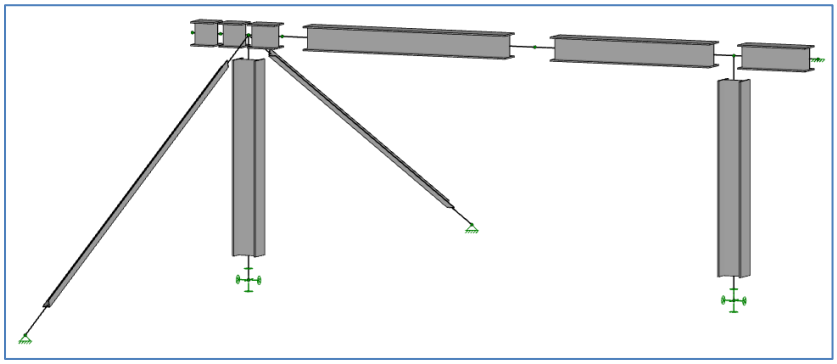

Figure 15: Existing PS-46

Recommendations

It is recommended to modify the pipe supports such that they will be able to adequately transfer the design loads from the pipe run to the foundation without failure. The recommendations are limited only to those 18 supports within the scope of study.

To address Deficiency 1, it is recommended to augment the existing braces where only one side of the support has been braced. Increasing the available strength of the braces would be the least intrusive method of increasing strength and reducing the utilization ratio. The simplest approach would be to stitch weld additional L2 x 2 x 1/4 angles to the inside of the existing L3 x 2-1/2 x 1/4 angles. Alternatively, additional bracing could be installed. However, this may not be feasible at all locations due to constraints

such as geometry, cross tunnels, and other physical objects. This recommendation is applicable to PS-80, PS-81, PS-83, PS-84, PS-86, PS-88, PS-89, PS-90, and PS-92.

Deficiency 2 is specific to PS-48 and PS-78 which are unbraced in the longitudinal direction. For both supports, it is recommended to provide bracing on at least one side to reduce the loads applied to the column baseplates. An L3 x 2-1/2 x 7/16 can be added from the top of PS-48 to the base of PS-47 and from the top of PS-78 to the base of PS-79. Using this larger size of angle will mitigate the concerns in Deficiency 1 without requiring nested angles or further alteration. It is also recommended to add a column on PS-78 under the 32-inch pipe and to provide a fixed connection between the beam of PS-48 and the gunite wall, either by welded baseplate or concrete embedment and tie-in. Altogether, these modifications will address the baseplate anchorage issues at PS-48 and PS-78. The modifications have been shown below in Figure 16 and Figure 17.

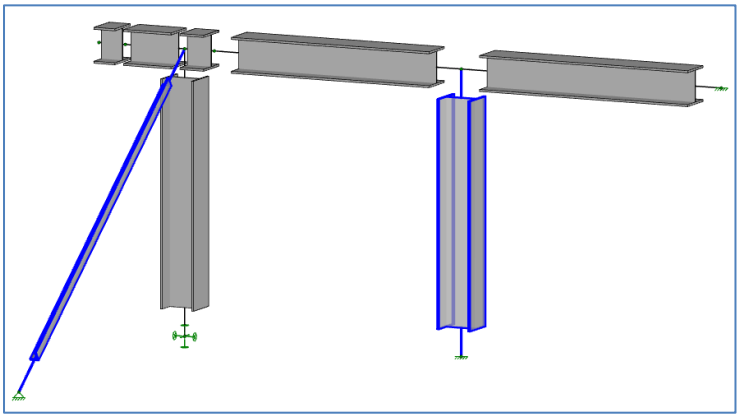

Figure 16: Modified PS-78

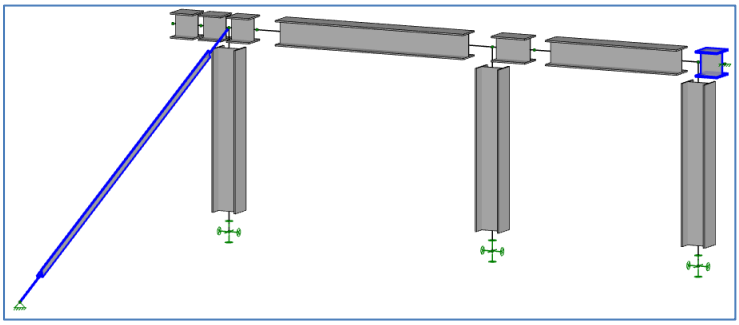

Figure 17: Modified PS-48

For Deficiency 3, the instabilities of PS-47 are considered in multiple parts. To address the baseplate anchor rod failure in PS-47a, it is recommended to add one L3 x 2-1/2 x 7/16 braces in each direction (lateral and longitudinal). This will minimize the bending moment applied to the baseplate and is the least intrusive repair. For the portion of this deficiency that pertains to PS-47, it is recommended to add one L3 x 2-1/2 x 7/16 diagonal braces in the transverse direction for stability. The brace could be attached at the base of the existing W-section knee brace and would only protrude less than 5 ft out from the vertical column. These recommendations are illustrated in Figure 18.

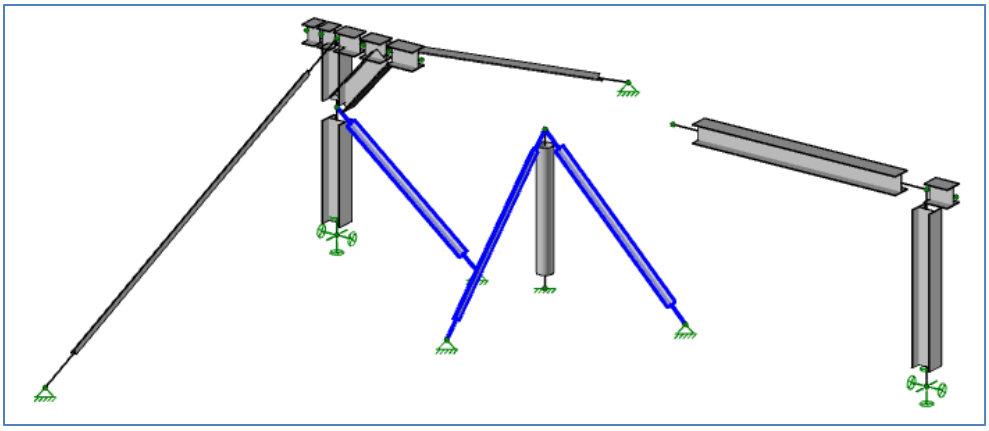

Figure 18: Modified PS-47 and PS-47a

Deficiency 4 can be addressed by adding an additional column to PS-46 under the (b -inch pipe. Properly sized, the column will support a large portion of the loading from the (b -inch pipe before it is shared by the other two columns. This will reduce the baseplate shear loading of the existing columns to acceptable levels. Figure 19 shows the modification of PS-46 to address this deficiency.

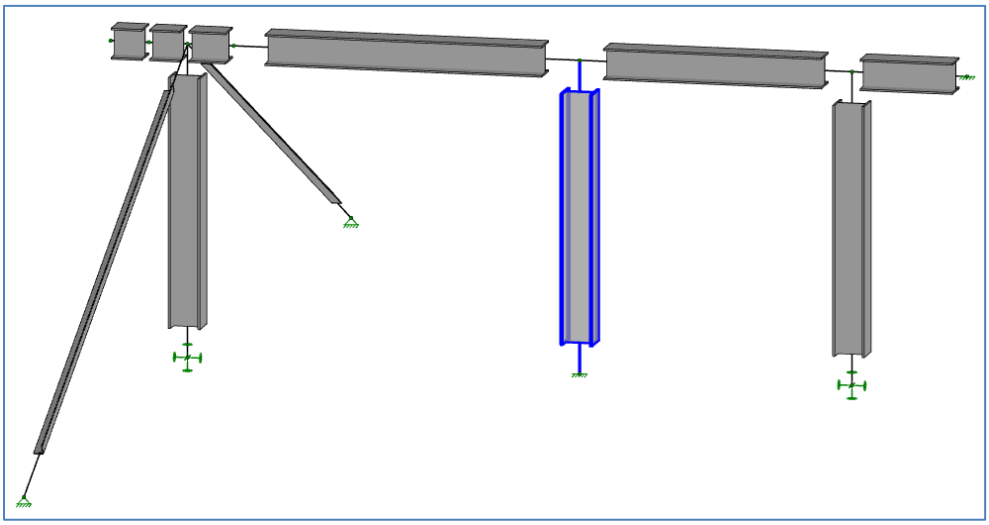

Figure 19: Modified PS-46

APPENDIX A
STRESS ANALYSIS MODEL SCREENSHOTS

CALCULATION METHOD: AUTOPIPE MODELING

The Red Hill lower access tunnel piping configuration and geometry (see Figure 1 below) were modeled according to 3D scans of the piping, CIR tank modification drawings for Tanks 13-14 and 17-18, and FY21 Emergent Pipeline Repair drawings for Tanks 1, 18-20, and the tee at Tank 5. The limits of the model were bounded between the end of the tunnel, near Tanks 19 and 20, and an anchoring bulkhead near PS-106. Tank lateral piping connected to each of the tanks was modeled as anchors at the tank walls.

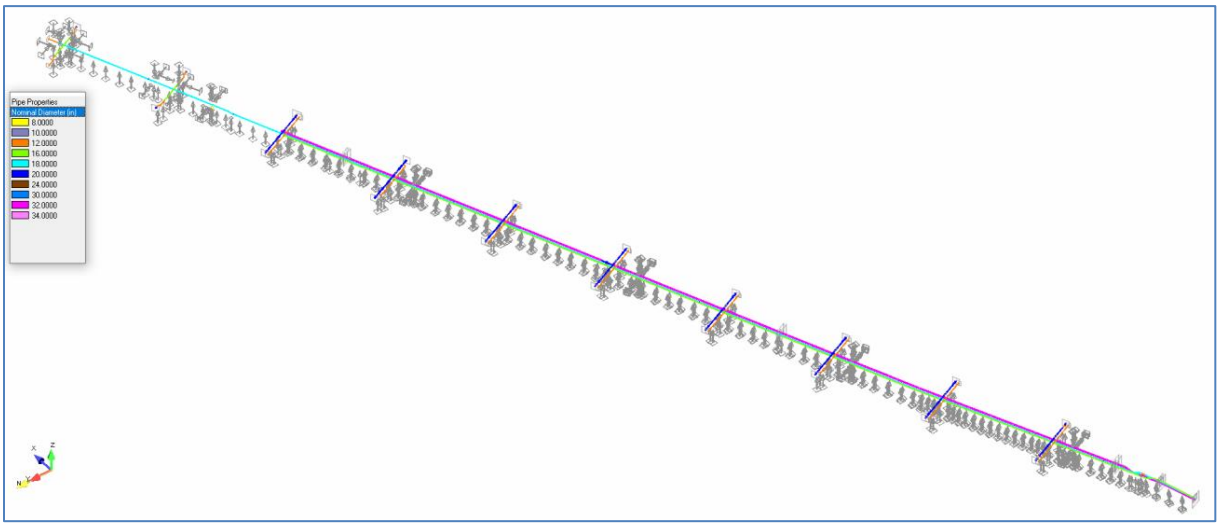

Figure 1: Lower Access Tunnel Piping Configuration. Tank 19 and 20 on the left, Tank 1 and 2 on the right.

In the lower access tunnel, there are three main transfer lines that carry fuel to and from Red Hill: a (b -inch F-76 line, an (b -inch JP-5 line, and a (b -inch F-24 line. The (b -inch pipeline connects Tanks 3-16, terminating at Tanks 15 and 16. The (b -inch pipeline connects Tanks 1-20, and the (b -inch pipeline connects Tanks 1-16, terminating at Tanks 15 and 16. A small piping segment at an (-inch tee was modeled and terminated at a bulkhead anchor.

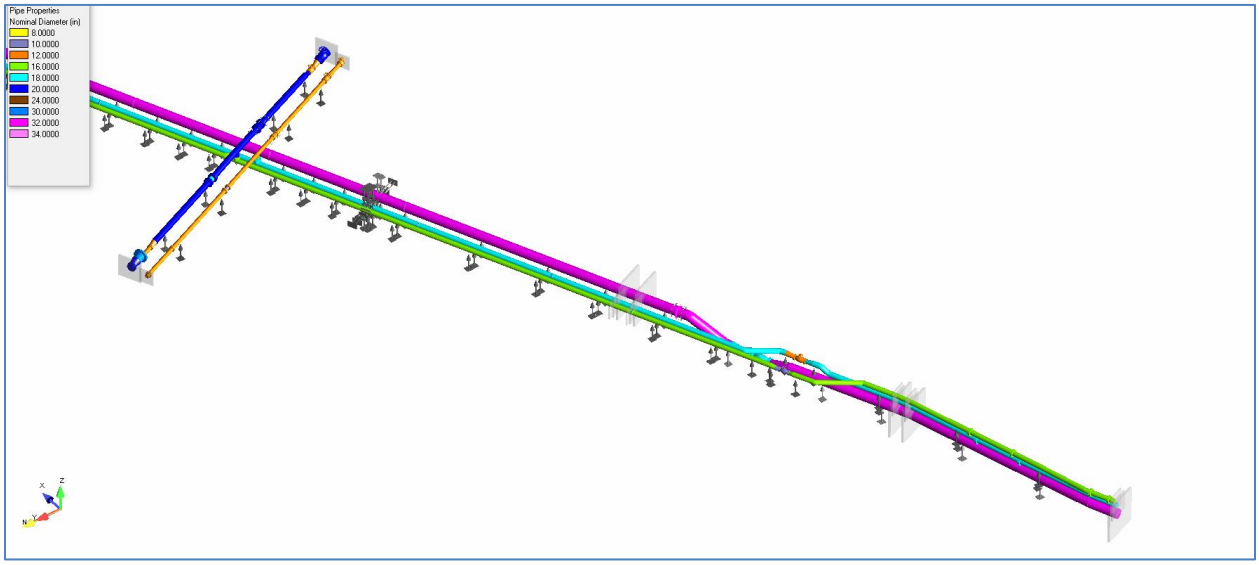

Figure 4: Tank 1 and 2 and Model Boundary Piping Configuration

AUTOPIPE RESULTS

Piping Stress

Stresses were calculated for ASME B31.3 code cases. The results are given as a ratio between calculated stress and allowable stress values. Any ratio over 1.00 exceeds allowable. Results shown in the figures below are due to piping load cases considering just an operating condition of defueling the facility. The operating pressure is due to the tank head, a pressure of 85 psi (P1).

Hoop Stress

The maximum allowable hoop stress is 20,000 psi or 20 ksi. The maximum calculated stress ratio is 0.44. This occurred in the (b -inch piping near PS-101 in the operating pressure (P1) case. The high stress concentration is due to mitered bends at this location.

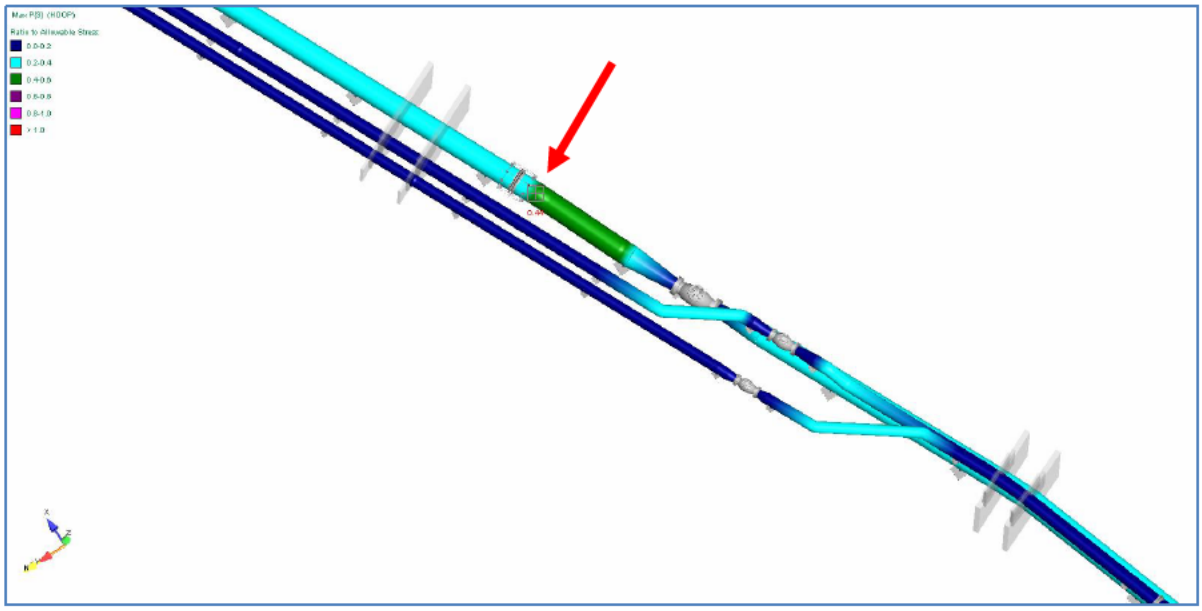

Figure 5: Hoop Stress

Sustained Stress

The maximum allowable sustained stress is 20 ksi. The maximum calculated stress ratio is 1.06. This occurs at the corridor of Tanks 1 and 2 on the (b -inch pipeline tee to the (b -inch lateral. This condition occurred while evaluating the effects of gravity combined with operating pressure (P1).

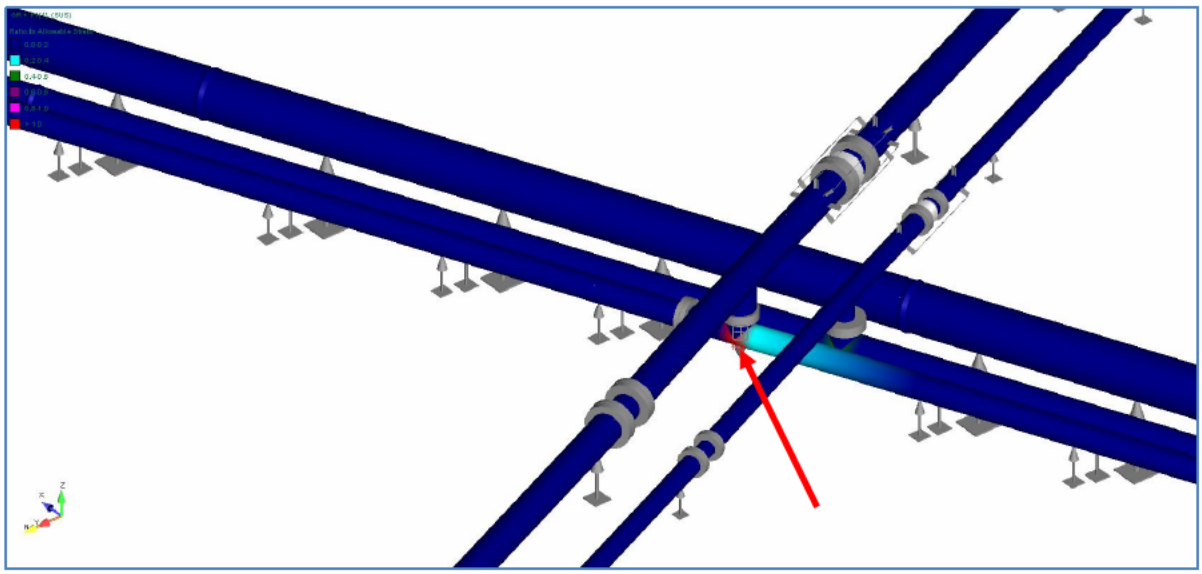

Figure 6: Sustained Stress

Occasional Stress (Seismic)

The maximum allowable occasional stress is 26.6 ksi. The maximum calculated stress ratio is 5.32. This occurs at the corridor of Tank 1 and 2 on the (b -inch pipeline tee to the (b -inch lateral. This condition occurred while evaluating the effects of the occasional load of seismic (E3) added to the sustained case.

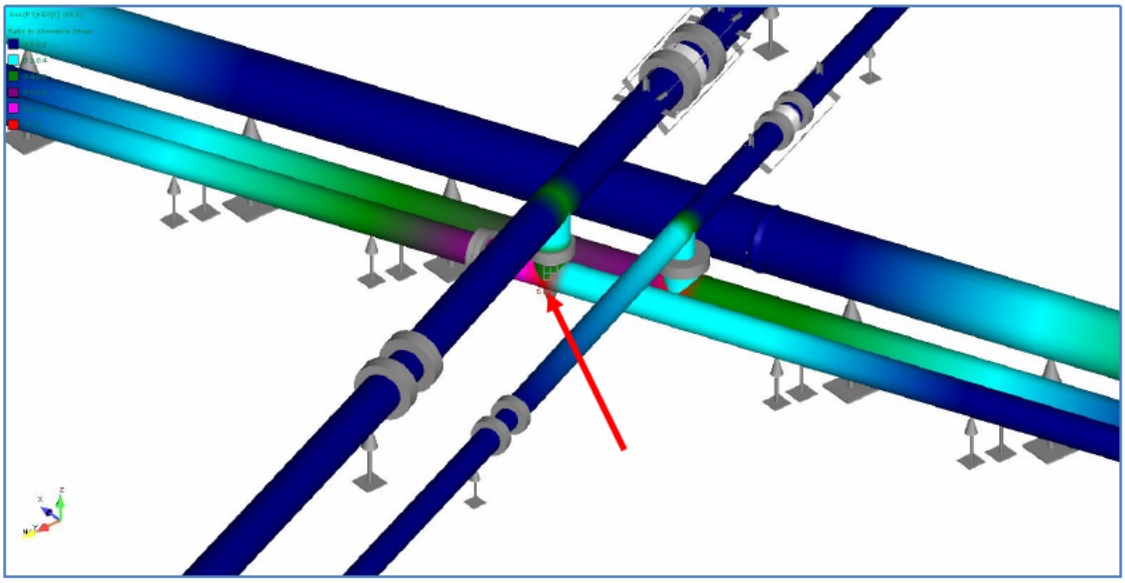

Figure 7: Maximum Occasional Seismic Stress

AutoPIPE Recommendations

To bring the lower access tunnel piping system into compliance with allowable code stress limits, modifications will need to be made to the existing piping system. The recommended modifications will allow the system to operate at pressures up to 85 psi, which will be sufficient to gravity-drain the tanks. The recommended changes will not be sufficient to maintain compliance with code stress limits at pressures above 85 psi, therefore operating the piping systems at pressures above 85 psi is not recommended. See Appendix D, Proposed Repairs Stress Analysis Summary, for the output report.

Spring Manufacturer:
NOTE 1: No soil supports present in the system.
Gap 1 : V-stop,Guide-V=down, Linestop,Incline,Tie/link=backward, Guide-H=Left, Rotation=Anticlockwise
Gap 2 : V-stop,Guide-V=Up , Linestop,Incline,Tie/link=forward , Guide-H=Right, Rotation=Clockwise
Stiffness units for rotation support: ft-lb/deg, all others: lb/in
Gap units for rotation support: deg , all others: inch
Breakaway force units for ultimate force gap support: lbf
K1-Ph-B and K1-Ph-F units for ultimate force gap support: inch
K1-Bckd, K1-Fowd, K2-Bckd and K2-Fowd are stiffness values for ultimate force gap support

ANCHOR DATA LISTING

APPENDIX F
MAPPED SPECTRAL RESPONSE FOR OCCASIONAL STRESS

Page Intentionally Left Blank

MAPPED SPECTRAL RESPONSE

Mapped spectral response value (S_s) corresponds to the latitude/longitude of the facility location. Structural load data according to UFC 3-301-01 provides a conversative value of S_s for the design of a facility. To determine a break point at which the calculated occasional stresses remained at or below the allowable occasional stresses (resulting in a stress ratio less than or equal to 1.00), an iterative calculation was run. The existing model was modified to include the proposed vertical support between Tank 1 and 2 (recommendation 2). Multiple seismic cases were set up with decreasing S_s (starting at S_s=0.5640).

The break point at which the calculated occasional stresses remained at or below the allowable occasional stresses corresponds to an S_s value of 0.11

Mapped Spectral Response for Occasional Stress							
Case	**Seismic Code**	**Vertical Factor**	**X (g)**	**Y (g)**	**Z (g)**	**S_s**	**Max Code Ratio**
