The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore

recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to

increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua I community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaiʻi has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the

background concentration of particulate matter (both $PM_{1.0}$ and $PM_{2.5}$) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for $PM_{1.0}$ is $2.01 \mu\text{g}/\text{m}^3$, well below the State standard of $150 \mu\text{g}/\text{m}^3$. The estimated concentration for $PM_{2.5}$ is $0.23 \mu\text{g}/\text{m}^3$, well below the Federal standard of $35 \mu\text{g}/\text{m}^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odor emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Dear Sirs,
Re: Hawaii Dairy Farms

At that February 2014 informational meeting held at the Koloa Kauai neighborhood center, Hawaii Dairy Farms representative Amy Hennessey told us their proposed dairy for Maha'ulepu valley is modeled after the grass-fed dairies in New Zealand.

Many of New Zealand's streams and rivers are contaminated by the dairy cow urine-manure run off during extreme weather events (heavy rainfall over extended periods) resulting in the poisoning of marine life. Those contaminated rivers and streams flow to the ocean.

New Zealand has closed beautiful beaches and posted health warning signs because the sand is now "impregnated" with dairy cow manure washed up onto their shoreline.

New Zealand was once a beautiful pristine island like Kauai. Kauai, like New Zealand, has extreme weather events (heavy rainfall over extended periods) annually. Therefore Hawaii Dairy Farms should not be permitted to operate a dairy of any size in Maha'ulepu Valley because of location's close proximity to certain south Kauai streams, ocean and beaches.

Hawaii Dairy Farms should be encouraged to submit a different site for their proposed dairy, away from all Kauai's rivers, streams, ocean and beaches, in order to produce milk for Hawaii families.

We Kauai families cherish our pristine beaches and clean ocean, and we all have a duty to protect Kauai's streams, ocean and beaches for Hawaii families.

A dairy operation is not a prudent agricultural proposal for the South Kauai coastal area. Hawaii Dairy Farms recently revised dairy operation proposal continues to lack sound judgement, reasoning and stewardship of Maha'ulepu Valley.

Sincerely,

Lori Decker

RE: Hawaii Dairy Farms Environmental Impact Statement Preparation Notice dated January 2015

Dear Ms McIntyre,

We have been assisting Kauai visitors from all over the world with Poipu accommodations for eighteen years. We have seen economic downturns as a result of the World Trade Center terrorism, massive construction in East Poipu, and the 2008 global financial meltdown. The Poipu visitory industry always recovered due to Poipu's pristine beauty, beautiful clean beaches and ocean, and its unique culture and heritage.

A proposed dairy of any size in Mahaulepu Valley will cause a certain and permanent economic disaster for the Poipu visitor industry. Word will quickly spread on social media not to go to Poipu - It stinks. Why would visitors come to Poipu? There are many other beautiful places to relax by a pool or on a beach that don't stink or have flies.

There will be certain noise pollution from crying dairy cows and calves during Poipu's quiet nights. There will be certain noise and light pollution from the proposed milking parlor during Poipu's dark nights and early mornings.

Please accept this letter as our written request that air pollution, noise pollution, light pollution, water pollution, water usage, and economic harm to local Poipu businesses and workers caused by an industrial dairy in nearby Malaulepu Valley all need to be addressed and answered by the EIS.

Sincerely,

Lori Decker
President

RE: Hawaii Dairy Farms Environmental Impact Statement Preparation Notice dated January 2015

Dear Ms McIntyre,

Our corporation was formed in Hawaii in 1980 for the purpose of owning Kauai real estate. The corporation currently owns a vacation rental home in the Poipu Kai Resort near the Grand Hyatt Kauai. That vacation rental home is designed for natural cooling. The cool trade winds blow through the home 80% of the year.

The air quality problems caused by gases emitted from the decomposition of dairy cow wastes and by the dust generated by animal activity and farming practices are well documented. We know these air pollutants can cause respiratory illness, lung inflammation and increase vulnerability to respiratory diseases like asthma.

Please accept this letter as our written request for you to ensure 1) the certain air pollution produced by the proposed dairy located directly **upwind** of our residential neighborhood, and 2) the certain economic harm to the **existing** Poipu property owners caused by the **proposed** for-profit industrial dairy located directly upwind of our residential neighborhood, be addressed and answered by the EIS.

Specifically the EIS should address the direct public health and economic harm from a 150, 300, 699 and a 2000 dairy cow operation. Also, the EIS should address the distance aerosolized manure and urine will travel with Kauai trade winds when effluent is spread through overhead irrigation.

Sincerely,

Lori Decker
President

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Lori Decker:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the sebacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhāʻulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

INVERTEBRATE SPECIES: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāʻulepū area, as well as the parasites and predators on site that control those species. Fieldwork was conducted during September 15-16, 2014. The entire study is included in Draft Environmental Impact Statement (EIS) as Appendix B.

CAVE AND LAVA TUBE INVERTEBRATES

There are no known caves or lava tubes found at or adjacent to the dairy farm property. The Kōloa Lava Tube System, which provides habitat for two endemic cave species, the Kaua'i Cave Wolf Spider and the Kaua'i Cave amphipod, is located several miles away from the dairy farm property. Both invertebrates are listed as endangered under the U.S. Endangered Species Act. Not all caves in the Kōloa area contain these invertebrates, as many do not contain the optimal climatological conditions required by these organisms. Neither the botanical and faunal survey nor the invertebrate survey revealed any evidence of lava tubes or caves on the property, and no such features have been reported for the area near the Hawai'i Dairy Farms (HDF) site. Thus no cave invertebrate species will be affected by the dairy farm.

INTRODUCED PREDATOR INSECTS

An invertebrate study of manure-associated insects was conducted for the Draft EIS. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently present at the HDF site. Pest insects such as flies can negatively impact livestock health and production, and are therefore actively managed to prevent stress and loss of productivity at dairy operations.

At the HDF site, two common flies were identified: the stable fly and the horn fly. Both of these flies are widespread throughout the Hawaiian Islands. The greenbottle fly was reared from manure taken back to a laboratory following the field survey. Additionally, flies known to exist on Kaua'i but not seen at the HDF site during the survey were identified and include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations.

In response to cattle-related insect pests, numerous species known to compete with the pests were introduced to Hawai'i between 1898 and 1982. Twenty species of predators and competitors to the horn fly were successfully established during that period. Cattle egrets break up dung patties while searching for prey, and were introduced to Hawai'i in the late 1950s to control cattle-associated insects. Extensive introduction of dung beetle species resulted in 14 dung beetle species becoming established on Kaua'i.

A healthy population of dung beetles can bury a dung pat in one to three days, which disrupts reproduction of flies such as the stable fly and horn fly. The stable fly requires approximately 21 days within the dung patty for the immature life stage (egg to pupa) to survive; the horn fly takes 10 to 20 days from egg to adult. Incorporation of the manure into the soil profile by dung beetles removes the habitat these flies require to complete their lifecycle. Research shows that 95 percent fewer horn flies emerged from dung patties containing a dung beetle species that has been identified at the HDF site. Proven control methods for the stable fly include parasitic micro-wasps and spreading out manure.

Among the invertebrates previously introduced to Hawai'i to combat livestock-related flies are extremely tiny parasitic wasps that prey on various fly species. The adult wasps could be described as the size of gnat. Using an ovipositor – described by lay people as a "stinger" – the female lays eggs in the larvae or pupa of flies. The male wasp has no such "stinger". See Draft EIS Section 4.11 for a photo providing scale for these tiny, non-stinging wasps.

To minimize potential establishment of pest flies or other insects, food waste generated during the construction phase will be bagged, covered, contained and disposed of in order to limit possible breeding habitat for flies. Inspections of building materials for ants or other insects will be conducted to prevent introduction of new pests to the HDF site. Short-term controls, including mechanical methods (e.g. sticky tapes or ribbons in the milking parlor, or traps with or without attractants) and chemical methods may be used to prevent short-term spikes in pest populations.

Insecticides and herbicides are non-discriminatory and kill beneficial as well as pest insects. Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Should chemical control be needed for short-term spikes in pest populations, application would be by those qualified, and in accordance with regulatory labeling requirements. HDF will implement long-term integrated pest management, which utilizes knowledge of the ancient food web among species by disrupting the manure habitat required to complete the fly life cycle. HDF and other ranchers on Kaua'i may choose to engage with the State

Department of Agriculture to translocation dung beetle species already introduced on Kaua'i to Māhā'ūlepū and other areas where manure-related flies may be a problem.

IMPACT OF SPRAYS ON BEES

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Honey bees are an essential part of any agricultural ecosystem, and were observed on site during the invertebrate species survey. Pesticides and herbicides can reduce populations of beneficial insects, which is why HDF will utilize an integrated pest management approach.

It is expected that honey bees will visit water sources set up for the HDF herd. Preventative measures will be built into any open water source to prevent bees from being trapped, and HDF will contact local beekeepers for advice regarding any bees or bee colonies encountered on site. Safe application practices for any unavoidable herbicide or pesticide will be utilized in order to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself, a local beekeeper will be contacted for advice and removal.

NOISE: Existing noise conditions of the project site and the surrounding Māhā'ūlepū valley area are evaluated in the Draft Environmental Impact Statement (EIS), along with anticipated short-term and long-term noise conditions associated with the dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai'i Department of Health (DOH) rules use the A-weighting sound network (dBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes. The Hawai'i Dairy Farms (HDF) site in Māhā'ūlepū Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition, occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 78 decibels or that cost a total of more than \$250,000. Mitigation measures to minimize construction noise will include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plascch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000

annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kauai, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kauai and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The

aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water

quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaula'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaula'i will increase county-wide by 17,300 residents by 2030. The South Kaula'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaula'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaula'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi

Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of driveway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural

fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water

masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua I community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two

separate milking cycles –moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of

worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

RE: RESPONSE TO PROPOSED ENVIRONMENTAL IMPACT STUDY

To Whom It May Concern:

As a resident of a home in the Po'ipu area I am extremely concerned about the environmental impact that HDF proposed dairy in Mahale'upu area will have on this pristine area. I feel it is imperative that I voice my strong objections to the proposed Hawaii Dairy Farm. As a travel professional I feel certain that the proposed HDF will profoundly and adversely affect tourism to Kauai. Should this happen many more jobs from the tourism industry will be lost compared to the very few created by the HDF.

The area of Mahale'upu in question is the oldest geological area in the entire state of Hawaii. It is an archeological area of significant importance. For that

reason alone it should be preserved. It has great cultural, spiritual and historic significance to the Hawaiian people and her culture, another reason for preservation of the area. This astoundingly beautiful area must be preserved.

The HDF dairy will undoubtedly affect the water quality of the stream that flows to the ocean. Pollution of the stream, land, watershed and ocean needs to be avoided at all cost!! Gravity will pull the polluted water runoff toward the ocean and kill the reef which is essential to support our fisherman, scuba divers and snorkelers as well as the pristine Mahale'upu beach. Loss of the coral reef is another example of the way we will lose tourists. When we lose tourism, we LOSE JOBS.

The EIS must include a study of the impact of HDF's trucks and traffic in and out of the Po'ipu area. HDF trucks will be hauling feed and fertilizer (as explained by HDF representative in the community meeting Feb 19). Trucks going in and out of the area will be carrying tanks full of milk as well as the empty trucks returning. Trucks will be going in/out of Po'ipu area carrying all the chemicals needed to clean the stalls twice each day and insecticides necessary for the cows. A traffic study must be done as to our current traffic and the increased traffic HDF would impose on the area. Our roads will suffer under the added weights of their trucks. Will HDF repair our roads? Along with the trucks will be their noise and air pollution. Please address the important issue of truck traffic in/out of the area. Milking stalls need to be thoroughly cleaned twice each day with harsh chemicals that will pollute the stream, watershed and run off into the ocean.

Air quality will be adversely affected by the trucks and the manure and anticipated collection ponds. With the manure will come the flies. Air and water will become polluted. I have been told the ponds will be lined with heavy plastic. There is no plastic on earth that will hold up to our hot, humid island conditions. What is the plan for overflow during our heavy rains and deterioration of the plastic pond liners?

Are we to believe that after the milk has gone to Oahu for pasteurization and bottling, it will return back to Kauai at an affordable price? If yes, the truck traffic would be increased even more. Have you seen the traffic problems that already exist on the island?

The EIS must also address the issue of flies and air pollution from the stench of the manure. It has been determined that the soil in the area is not absorbent meaning the cow urine as well as rain water will run off into the stream and ultimately end up on the ocean. What a travesty to think of the pristine Mahale'upu beach as a cesspool of cow droppings.

Please consider a different area for HDF's project that will not adversely affect the long established environmentally friendly way of life on Kauai.

Sincerely,

Catherine DeMichiel,

Travel Consultant

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kauai', Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Catherine DeMichiel:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau,

and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plach Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the

development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E

and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane

plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauai region (the Kōloa - Po'ipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running

through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or

maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation, and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater

and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

TRAFFIC: The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site is via Māhā'ulepū Road, a two-way, two-lane road, which is accessible from Kōloa Road (Highway 530) via Ala Kinoiki Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from Māhā'ulepū Road.

Roadways in the project area operate smoothly with no periods of heavy traffic. On average, traffic in the region is much lower than urban areas in the state due to the low population of Kaua'i and rural agricultural demographics of the south Kaua'i area and Māhā'ulepū. Traffic on Māhā'ulepū Road consists of agricultural vehicles, residential and resort visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be

generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhā'ulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoiki Road and Kōloa Road was 8,000 and 6,500 cars daily; HDF-related traffic would add less than one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoiki Road and Kōloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawai'i Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure

application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be

dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid,

reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

addition pasteurized milk definitely commands a significantly higher price from Asia making a return to Kauai even more questionable. Anyone who believes the Hawaii Dairy Farms statement as being a major intent for establishing a dairy on Kauai is a prime candidate to be sold resort property in the heart of the Great Dismal Swamp, which is what Maha'ulepu could be looked at within a short period of time should the dairy be approved.

The island of Kauai has other abundant suitable agricultural acreage upon which to establish a dairy should one be needed so badly. I can only scratch my head in wonderment why this acreage in Mala'elepu Valley, which possesses such a diverse historical, cultural, spiritual and environmental significance could have been chosen for an untested theoretical experiment that has never been proven to be a success anywhere in the world.

In summation, the dairy has not even been built yet but it has already provided a negative impact in the community through Hawaii Dairy Farm's attempt to strong arm their desire down the throat of the people it sought to appeal to. A terrible start to a terrible idea. This dairy must not be allowed to be built in Maha'elepu Valley.

Sincerely,

Robert P. DeMichiel

February 22, 2015

To Whom It May Concern

I reside at 1831 Poipu Road, in Koloa. My home is located approximately 1-1/2 miles from the proposed Dairy Farm. The Dairy Farm will negatively impact my property value and my ability to enjoy the beautiful area I chose to retire to. I am sure what I have to share is not new but I felt compelled to put my thoughts on paper and send them to all concerned.

I am writing to voice my objections to the planned use of 578 acres of pristine land in the Maha'ulepu Valley for a very dangerous, unproven experiment. This project would violate every established criteria used in determining if a significant impact would result from the land's intended use. The sheer contention that because the land is zoned agricultural does not automatically make it subject to being abused in the manner that Hawaii Dairy Farms intends.

The many newspaper articles have talked about the amounts of manure and urine, smells that this could create the potential for flies and the run off of contamination into streams and eventually the ocean. These arguments against the planned use of the property have been numerous presented and probably stated more eloquently then I can in this letter.

I wish to issue strong objection with a point that I feel is an absolute falsehood perpetrated on the public by Hawaii Dairy Farms: namely the Hawaii Dairy Farms justification for being. "Fresh milk for Kauai/Hawaii families". Not sure how this can happen since all potential milk will have to be shipped to Oahu with there being no pasteurization facilities on Kauai. Once this happens all raw milk loses its identity as to its original source thus making returning it back to Kauai somewhat problematic. In

Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kauai, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Robert P. DeMichiel:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S.

Robert P. DeMichiel

Page 2 of 13

Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The

management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times: State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Placsh Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy

cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic

material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and

groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the

State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the

potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator

bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area,

- soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kauai, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

HDF, Department of Health, and Group 70

I think that locating a mega-dairy above the beautiful pristine area, Mahaulepu will be an irrevocable mistake! Here are my objections to HDF's plan that includes an eventual herd of 2,000 dairy cattle. This affects me, because I live on the South Shore, and I believe it will affect all of Kauai.

Because of the amount of waste and the unproven waste management system that HDF plans to use, I believe that the estimated 51 million Lbs of wet manure and 600,000 gallons of urine over a 6 months period, will be an uncontrollable amount, regardless of the effluent ponds, which other mega-dairy companies have found to leak. The runoff will eventually drain into streams that run into the ocean and will cause irrevocable damage to the fragile coral colonies that are currently struggling to survive there. Mahaulepu, and Poipu Beach, which are considered world class attractions and known for good swimming, will be ruined - lost forever.

The state of Hawaii is devising a policy that will mandate that all Kauai residents must convert to septic systems, in order to protect the waters that surround the island. Imagine the damage from run-off from 2,000 cows, should HDF's system fail. An estimated 51 million Lbs. of wet manure and an unthinkable 600,000 gallons of urine over a six months period, would find its way into our ecosystem. Also the National Tropical Botanical Garden, which is located on the South Shore and extends to the ocean, is home to thousands of rare plants in carefully controlled Microsystems, could be lost forever. Certainly there is some other place, possibly on a bigger island, for an experimental mega-dairy.

Considering the economic wellbeing of the community, imagine the impact of biting flies and dairy stench on the visitor industry, which is the largest business enterprise in the South Side economy. No more dining on restaurant lanais, strolling to shops, sitting on hotel balconies, walking on the beach, watching the sunset, golfing at the Grand Hyatt. Visitor services of many kinds will no longer be able to make it.

So, it won't take long for the travel websites to "get wind" of "the big problem on Kauai". Tourism, upon which we rely will be a thing of the past. Just when we were getting a handle on unemployment, hundreds of visitor industry workers will be without work. This would be disastrous for a small island, and could result in more burglaries as people are unable to find work.

Housing values would be sure to drop. People's life savings down the drain - all because a billionaire is unwilling to look at relocating his business venture. Home values in other areas located near mega-dairies have suffered.

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kauai, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Diane deVries:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S.

As stated at the EIS presentation on Feb. 19th 2015, HDF plans to leave a large portion of excrement on the ground to fertilize the feed grass. This would be on clay soil, and would it would eventually find its way to streams, the ocean, and also into near by wells. Two of these are the drinking water sources for the town of Koloa, and area of Lawai. HDF makes no mention of the proximity to the wells in their reports. This problem of contamination would certainly be heightened during a hurricane or even a big storm, such as Kauai residents refer to as "Forty Days and Forty Nights" that we experienced in the past. Even small storms could result in contamination.

Our wonderful world class environment is sure to be degraded by the addition of mega amounts of Methane gas, effluent run-off, and trampling cattle hooves. Also in need of consideration is the extremely rare Blind Cave Spider, one that has developed without eyes, and lives only in a cave on the Mahaulepu coast line. This extremely rare creature is currently being studied by scientists. Disturbing it's ecosystem and the special conditions that it needs to thrive, would result in a huge loss to all of Kauai. Fresh and costal waters that we have respected need to be kept in good condition and out of harm's way.

Our already over burdened roadways will surely be impacted by tanker trucks carrying milk for export from of Kauai. No plan to handle this in the HDF report. It seems that off island business owners are not really concerned with how their business impact our small island.

As per the above stated examples, an experimental mega-dairy is inappropriate for the Mahaulepu area. HDF seems insensitive to this fact, and to the realization that their business is not welcome at this location. The New Zealand Mega-Dairy Model is reportedly a huge failure. We don't need a mega-failure on Kauai.

Sincerely,

Diane DeVries

Diane de Vries

Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The

management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhāulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kāua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kāua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhāulepū region during and following the hurricanes that affected Kāua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhāulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds

regulatory requirements, with containment in excess of the major rainfall events recorded on Kāua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhāulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kāua'i may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests

in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

INVERTEBRATE SPECIES: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators on site that control those species. Fieldwork was conducted during September 15-16, 2014. The entire study is included in Draft Environmental Impact Statement (EIS) as Appendix B.

CAVE AND LAVA TUBE INVERTEBRATES

There are no known caves or lava tubes found at or adjacent to the dairy farm property. The Kōloa Lava Tube System, which provides habitat for two endemic cave species, the Kaua'i Cave Wolf Spider and the Kaua'i Cave amphipod, is located several miles away from the dairy farm property. Both invertebrates are listed as endangered under the U.S. Endangered Species Act. Not all caves in the Kōloa area contain these invertebrates, as many do not contain the optimal climatological conditions required by these organisms. Neither the botanical and faunal survey nor the invertebrate survey revealed any evidence of lava tubes or caves on the property, and no such features have been reported for the area near the Hawai'i Dairy Farms (HDF) site. Thus no cave invertebrate species will be affected by the dairy farm.

INTRODUCED PREDATOR INSECTS

An invertebrate study of manure-associated insects was conducted for the Draft EIS. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently present at the HDF site. Pest insects such as flies can negatively impact livestock health and production, and are therefore actively managed to prevent stress and loss of productivity at dairy operations.

At the HDF site, two common flies were identified: the stable fly and the horn fly. Both of these flies are widespread throughout the Hawaiian Islands. The greenbottle fly was reared from manure taken back to a laboratory following the field survey. Additionally, flies known to exist on Kaua'i but not seen at the HDF site during the survey were identified and include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations.

In response to cattle-related insect pests, numerous species known to compete with the pests were introduced to Hawai'i between 1898 and 1982. Twenty species of predators and competitors to the horn fly were successfully established during that period. Cattle egrets break up dung patties while searching for prey, and were introduced to Hawai'i in the late 1950s to control cattle-associated insects. Extensive introduction of dung beetle species resulted in 14 dung beetle species becoming established on Kaua'i.

A healthy population of dung beetles can bury a dung pat in one to three days, which disrupts reproduction of flies such as the stable fly and horn fly. The stable fly requires approximately 21 days within the dung patty for the immature life stage (egg to pupa) to survive; the horn fly takes 10 to 20 days from egg to adult. Incorporation of the manure into the soil profile by dung beetles removes the habitat these flies require to complete their lifecycle. Research shows that 95 percent fewer horn flies emerged from dung patties containing a dung beetle species that has been identified at the HDF site. Proven control methods for the stable fly include parasitic micro-wasps and spreading out manure.

Among the invertebrates previously introduced to Hawai'i to combat livestock-related flies are extremely tiny parasitic wasps that prey on various fly species. The adult wasps could be described as the size of gnat. Using an ovipositor – described by lay people as a "stinger" – the female lays eggs in the larvae or pupa of flies. The male wasp has no such "stinger". See Draft EIS Section 4.11 for a photo providing scale for these tiny, non-stinging wasps.

To minimize potential establishment of pest flies or other insects, food waste generated during the construction phase will be bagged, covered, contained and disposed of in order to limit possible breeding habitat for flies. Inspections of building materials for ants or other insects will be conducted to prevent introduction of new pests to the HDF site. Short-term controls, including mechanical methods (e.g. sticky tapes or ribbons in the milking parlor, or traps with or without attractants) and chemical methods may be used to prevent short-term spikes in pest populations.

Insecticides and herbicides are non-discriminatory and kill beneficial as well as pest insects. Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Should chemical control be needed for short-term spikes in pest populations, application would be by those qualified, and in accordance with regulatory labeling requirements. HDF will implement long-term integrated pest management, which utilizes knowledge of the ancient food web among species by disrupting the manure habitat required to complete the fly life cycle. HDF and other ranchers on Kaua'i may choose to engage with the State

Department of Agriculture to translocation dung beetle species already introduced on Kaua'i to Māhā'ulepū and other areas where manure-related flies may be a problem.

IMPACT OF SPRAYS ON BEES

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Honey bees are an essential part of any agricultural ecosystem, and were observed on site during the invertebrate species survey. Pesticides and herbicides can reduce populations of beneficial insects, which is why HDF will utilize an integrated pest management approach.

It is expected that honey bees will visit water sources set up for the HDF herd. Preventative measures will be built into any open water source to prevent bees from being trapped, and HDF will contact local beekeepers for advice regarding any bees or bee colonies encountered on site. Safe application practices for any unavoidable herbicide or pesticide will be utilized in order to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself, a local beekeeper will be contacted for advice and removal.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila* *musophila*, the only Kaua'i species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950

to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōba-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kimoiki Road between Kōba and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plascq Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11

indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa

series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF

prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing-agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainage ways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainage ways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

TRAFFIC: The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions along with potential impacts of the dairy farm construction and operation. Primary access to the site is via Māhā'ulepū Road, a two-way, two-lane road, which is accessible from Kōloa Road (Highway 530) via Ala Kinoliki Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from Māhā'ulepū Road.

Roadways in the project area operate smoothly with no periods of heavy traffic. On average, traffic in the region is much lower than urban areas in the state due to the low population of Kaua'i and rural agricultural demographics of the south Kaua'i area and Māhā'ulepū. Traffic on Māhā'ulepū Road consists of agricultural vehicles, residential and resort visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhā'ulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoliki Road and Kōloa Road was 8,000 and 6,500 cars daily; HDF-related traffic would add less than

one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoliki Road and Kōloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawaii Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing

system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odor emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population and approximately 44 hours per year. The parameters used in the analysis were

intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis; however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kauai; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawaii, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kauai in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawaii Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawaii Dairy Farms will create a commercial scale pasture-based dairy operation in Hawaii, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kauai, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

RE: Hawaii Dairy Farm EIS for Maha'ulepu Valley, Kauai

Aloha Ms. McIntyre,

I, David DeZerega, am a home owner and rental property owner in Koloa, HI. I am writing to comment on the scope of the EIS by "Group 70 International, Inc." for "Hawaii Dairy Farms" proposal to ultimately have a 2,000 cow dairy on 578 acres in Maha'ulepu valley, Kauai, Hawaii.

My first concern is why is the trigger for the EIS voluntary, when the EIS presentation states the dairy is a "LARGE CONCENTRATED ANIMAL FEEDING OPERATION". My understanding is that a CAFO is required by law to trigger an EIS. Should not the EIS be statutorily triggered?

I am concerned about the alternatives being prescribed prior to the EIS process rather than developed in the process. Possible alternatives could be a smaller herd size on the allotted land, an alternative site or whatever the EIS process produces. We should not be limited to the THREE ALTERNATIVES described in the presentation.

The presentation says that excessive waste will be shipped offsite. I worry that if there is excessive waste that it not effect the well water nor the coastal reef. Safeguards should be put into place and provided by HDF if approved. In addition a remediation process should be prescribed.

I worry about the influx of flies caused by the on site utilization of the fecal and urinary waste of the cows. Flies have a 2-5 mile radius from the site and that would affect my homes in Koloa. In addition to this pollution I am concerned with the methane pollution and hope that will be addressed.

Maha'ulepu is one of the most pristine and beautiful places on earth and I would not like to see it degraded.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear David DeZerega:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPEN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPEN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and

irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali

formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed, rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Portable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of

groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built

facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-foot from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to

create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the

Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19.2 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

GREENHOUSE GASSES: Draft Environmental Impact Statement (EIS) Sections 4.19 and 4.26 address the potential for greenhouse gas emissions by Hawai'i Dairy Farms (HDF). Estimates of GHG emission rates from a pasture-based dairy, including methane and nitrous oxide, were calculated using the 2006 Intergovernmental Panel on Climate Change (IPCC) Guidelines for National Greenhouse Gas Inventories. Parameters for Oceanic dairy cattle in warm climates were selected as most applicable to conditions at HDF. Long-term operational impacts were modeled using the IPCC guidelines and conversions, and estimated the emissions potential for GHG at the dairy at the committed herd size of 699 milking cows to be 2,693 CO₂e metric tons per year. This equates to roughly 1.02 percent of the utility power generation sector on Kaua'i in 2013, which does not include vehicle emissions and other GHG emitters on the island.

Potential GHG emissions for HDF at the contemplated herd size of up to 2,000 milking cows was modeled as described in Section 4.19.3 using the IPCC guidelines and conversions. The estimated total of 7,702 CO₂e metric tons per year (8,490 tons) is 5,009 CO₂e metric tons (5,521 tons) greater than the committed herd size of 699 milking cows. This equates to an increase equivalent to 1.91 percent of GHG produced on Kaua'i for power generation by the utility in 2013 (KIUC, 2014). Power generation does not include vehicle emissions and other GHG emitters on the island.

While the presence of cows may increase GHG, a long-term beneficial impact of the grazing fields is the sequestration of carbon as CO₂ captured by the process of photosynthesis by the grass. According to recent studies in the Soil Science Society of America Journal, converting formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, which enhances soil quality, grass production, and has the potential to offset up to one-third the annual increase in CO₂ production of an area.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis; however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

I own a home within a few miles of the proposed industrial sized New Zeal and style two thousand cow dairy being planned for Maha'ulepū Valley on the island of Kauai. I have long worked with Malama Maha'ulepū as a volunteer to preserve the precious pristine area of Maha'ulepū for future generations, an area that has been found deserving of such preservation in a federal National Park Survey commissioned by the late senator Inouye. I am extremely concerned about the impending disastrous impact such a dairy will have on both the environment and economy of the surrounding area of residential Koloa town and the world famous Po'ipu resort area.

One of my concerns is with the enormous amount of feces manure and urine waste per cow per day for 365 days per year. The soils are such that they cannot use the amount of waste to fertilize the pasture grasses and so the system is not zero discharge. According to the NRCs study of June 2014, three fifths of the soils within the acreage have been found to be largely clay. The dairy is uphill from the ocean, rainfall per year is significant and runoff of waste into the ocean is very likely. Other soils can carry waste pollution into fresh water wells used by the town of Koloa/Poipu for drinking water.

Additionally, there are protected animals such as the monk seals and marine life of the reefs that will be adversely impacted by polluted waters. Traditional fishing will be affected. The night lighting for milking will negatively affect the shear water birds. There are cultural and historical areas of importance that may be harmed.

There is no known abatement plan for the thousands/millions of flies that will be attracted to the enormous waste. The winds are from the northeast and will blow the stench of the dairy into the resort and residential areas. If visitors stop coming because of the polluted beaches, stench, and flies, businesses will fail, thousands of workers will lose jobs, property values will plummet and the country government will lose a large portion of its tax base. The dairy will be an economic as well as environmental disaster.

The dairy as planned is too big a project (and in fact, is experimental since even the New Zealand investors say 1000 cows should have 1000 acres not 2,000 on 587 acres). The dairy is not only too large and experimental, it is in the wrong place. A populated area and an environmentally precious coastline is a poor choice for such an endeavor.

Finally, HDF claims to be grass fed which is not true since thirty percent of the feed will be grain. It may or may not produce milk for local consumption since once it is shipped off island for processing the milk can be sold anywhere in the world.

A voluntary EIS can be altered from one that is required by the state and cannot be challenged in court. All the technical studies will be done by groups chosen by HDF's group 70 International. None of this inspires confidence that the EIS will be objective.

I am writing this letter to insure that I have the right to comment on the EIS in the future.

Sincerely, Sara DeZerega, Koloa

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Maha'ulepū Road
Kauai, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Sara DeZerega:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Maha'ulepū Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S.

Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The

management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaula Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luuluaie Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasz Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of

approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were

conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kaiāheo districts), water use in 2035 is projected to be 3.24 MGD, an

increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has

completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter

periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

SUBJECT: Hawaii Dairy Farms' Voluntary EIS Preparation Notice

Aloha Laura McIntyre and Jeff Overton,

I wish to be a consultant party for the draft EIS.

We live in Koloa and I am a longtime volunteer with Malama Maha`ulepu. I have worked on many stewardship activities at Maha`ulepu, from weeding and watering native plant restoration projects to beach clean-ups. I have helped with educational outreach for this beautiful undeveloped coastline from participation in the Koloa Plantation Days' events to powerpoint presentations for students.

I love Maha`ulepu and see the priceless value in this rich cultural landscape as an undeveloped area for public access, cultural restoration and compatible uses. We must have a place where people can enjoy personal restoration and recreational activities. Our local community, fisherman, waterman, and visitors count on there being an undeveloped area of original landscape.

As much as I would love to see compatible agriculture on this rich valley, like a diversified food forest, the Hawaii Dairy Farms plan carries great concern.

From the beginning of our knowledge about the plan for a dairy in Maha`ulepu Valley, I approached with an open mind. We want ag. it is zoned ag. I rode along on a small tour in February, 2014. With each question and answer, my concern was growing. The herd size, the concentrated grazing areas, the conditions, the soil types and the containment

RECEIVED

FEB 25 2015

GROUP 70 INTL

facts were much different than what we were presented earlier. I am very concerned about the impacts. Specific points that I believe need to be addressed in the draft EIS are as follows:

1. I am very concerned about the potential for water quality contamination of our drinking water and run off. This carries concerns also about the public health of Koloa/Poipu residents and our tap water and beaches and aquatic life.
2. I am concerned about the location of the milking area and waste ponds. They are very, very close to the aquifer. I would like to see the data examined for the harmful impacts of the waste ponds in regards to leaching into the aquifer and overall cleanliness of holding waste in this manner.
3. The amount of water consumed for operation is enormous. The dairy may feel they own the self-replenishing aquifers and all the water they want from the Waita Reservoir, but they don't. I question why we would use such a large amount of our water resources on yet another type of agriculture that leaves our island and gives us nothing to eat. Please include in the EIS a water usage analysis.
4. The EIS must include the consideration of other reasonable locations both on Kaua'i and perhaps also on the other islands, including the island it will be ultimately processed and packaged on.
5. The EIS must include detailed and accurate soil and hydrological data of the entire ahupua'a of Maha'ulepu. It must address the complete watershed, including the lava tube system, and show that no run off will occur under any circumstance.
6. We must include study and disclosure about what integrated pest management plan for fly control, and if this would require the potential for pesticide application.
7. The importance of Maha'ulepu to the south shore for the residents, fisherman, geologists, archeologists, the students and the visitors, should require that bonding mitigation measures are in place, such as an environmental remediation bond and continual monitoring protocols. Such monitoring and sampling must include community involvement and disclosure.
8. The EIS must include environmental indicators and metrics to determine what size of a herd the land and resources can support without damaging the ecology of the valley and the surrounding towns.

9. The EIS must include plans for site remediation for when the lease ends. Site remediation must include a guarantee from HDF that Maha'ulepu will be fully restored to its current condition. A remediation fund should be required to cover the costs of damage or impact to its natural state.

10. We must study the impacts on cultural practices, cultural sites, hunting, and hiking. The ahupua'a of Maha'ulepu as the last remaining, easily accessible, undeveloped coastline deserves our highest stewardship. It is a natural and living museum. It is an important example of how things used to be. It provides unparalleled beauty and outdoor classroom for our local children.

11. I would like for the EIS to include encouragement for the HDF plan to avoid the importation and feeding of genetically engineered corn for cow feed. Consumers are seeking out truly grass fed dairy milk and they avoid milk from GE grains. Alternatives exist, if the milk produced did not include GE grains, there could be a local use for the milk fat to remain on island and become a value added product like yogurt.

Please keep in mind that we would know the importance of food security and ecological soundness and historical conservation. I feel that this plan from HDF provides none of these measures. It is the wrong location for a model that takes from important resources and leaves the community with only negative impacts. I can see no community benefit.

Thank you for incorporating these comments into the draft EIS scoping project. Please remember, or visit, this special site. I am sure you understand the significance of this area, not only our community, but to future generations.

Mahalo and aloha 'āina,

Jeri Di Pietro

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Jeri Di Pietro:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system

Jeri Di Pietro
May 26, 2016
Page 2 of 14

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data

the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kāena Clay Brown Variant at 29 percent, and Luualaei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due

to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 16E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the

exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million

gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The

Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8

inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each

reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2), grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient

contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Kauai Dairy EIS

To Whom It May Concern-

It should be obvious that a dairy will have significant impact on the environment and human health, unless many, many safe guards are put into place in advance and protocols for monitoring. Of note, what happens to all the bovine excrement? How is it treated or is it treated so as not to contaminate ground water and our oceans? How does a dairy alter the environment and what can be done to insure that the environment is not altered? Who monitors this? And lastly, what is the effect on humans? A dairy will attract flies and other insects, which can carry disease. What safe guards will be put in place to help guarantee that the impact on humans is non-existent?

 Environmental Impact Statement Preparation Notice
 Māhā'ulepū Road
 Kāua'i, Hawai'i
 TWK: (4) 2-9-003: 001 portion and 006 portion
 (4) 2-9-001:001 portion

Dear Michael Diamant:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kāua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations

(CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the

cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and

other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day.

Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development.

The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the

current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ūlepu will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality

monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Dear Sir or Madam,

I personally feel like the proposed planned dairy for Mahalepu is an unsafe, overreaching plan that should be put on hold at this time until an independently contracted EIS can be done. I believe that the concentrated rotational dairy proposed by HDF is far too much waste to add safely to the area in question.

Soil testing needs to be taken seriously, with the long-term effects of grazing management systems and their impacts on soil quality and water quality in local wells preeminent.

A Voluntary "EIS" is a travesty to those concerned with the long-term viability of Kauai's Tourism in the Poipu area. A large, high-density dairy is not what was likely envisioned for Mahalepu's agricultural zoning and is also extremely close to residential zoning.

Kauai can support good neighbor business when care for local resources and not just a profits first mentality is part of the mission statement.

Kauai has supported small dairies in the past with the largest herd of less than 500. These dairies were located in more rural locations with herds rotated to different pastures. The proposed dairy in Mahalepu is a completely different practice and will have much more concentrated effect on the pasture land in question.

Kauai will change with the times however it is all our concern as people of Kauai to steward a future that balances new opportunities without losing others or perhaps creating insolvable problems.

I am disappointed that our Department of Health is not taking part in this EIS.

Jay Dorrance

 Environmental Impact Statement Preparation Notice
 Mahā'ulepū Road
 Kaua'i, Hawai'i
 TMK: (4) 2-9-003:001 portion and 006 portion
 (4) 2-9-001:001 portion

Dear Jay Dorrance:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

Your comments were received by the State of Hawai'i Department of Health Environmental Planning office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental

planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions,

supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and

diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Dear Mr. Overton,

My family has lived in Koloa, Hawaii for decades. We swam at Poipu beaches and often frequent the area to dine or for recreation. It's home; a bastion of peace, safety and comfort. The proposed dairy in Maha'ulepu, as we see it, will completely destroy life on the South Side and beyond as we now know it.

Four wells that serve as sources of public drinking water for Koloa and Poipu are close to the area of the dairy designated to receive pumped manure sludge when draining the effluent ponds. Scientists specializing in agricultural operations have issued a dire warning: The risk of water CONTAMINATION from migrating bacteria and nitrates would be great. This translates into not only exposing South Side residents to contaminated drinking water but also the thousands of visitors who arrive annually and infuse the economy with millions of dollars.

A herd of 2,000 dairy cows (Phase II) will produce millions of pounds of manure monthly. HDF's plans claim zero waste elimination but the NRCS's June 2014 study, "Custom Soil Resource Report", concludes that the soil on this site is "very limited" in its ability to absorb animal waste and risk of runoff is "high" or "very high". Millions of pounds of runoff flowing into the ocean waters of the South Shore - a monumental environmental and economic disaster in the making for the entire South Shore. HDF's plan calls for the creation of 10 - 15 new jobs. And what of the thousands who will lose jobs as we watch the demise of the hotel and visitor industry and other related businesses - restaurants, those engaged in water sports, sightseeing, etc. ?

Entomologists have stated that the dairy will spawn billions of flies within months - the biting variety with serrated mouths that live on blood - and they will inhabit a radius of five miles. What plans does HDF have in place to address this serious health threatening situation?

Maha'ulepu's spectacular landscape is home to endangered species, irreplaceable natural, cultural, historic, agricultural and scientific resources - petroglyphs, a heiau and unexcavated sites are amongst the treasures to be found in the area. Surely we owe it to the Native Hawaiians to honor all that is sacred to them. In honoring them, we preserve for ourselves that which is irreplaceable. Endangering or destroying these sites would be an unconscionable act.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Ellen Ebata:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S.

It has been estimated that homes located near dairies can lose up to 88% of their value depending on proximity and whether they're upwind or downwind of the operation and the number of days per month when there's an odor. That many work at two to three jobs to meet mortgage payments is no secret; plummeting values of our homes is a nightmare we should never have to face. I wonder what buyer would jump at the following ad: House for sale in South Side, prime location downwind from large dairy, polluted drinking water, scent of eau de cow manure waiting through air, property infested with biting flies, all conditions pose significant health threats.

The dairy will require millions of gallons of water daily for its operations. What entitles this proposed operation to draw from Waita Reservoir, a resource that is meant for residents?

Hurricane season brings fearsome weather conditions and the dairy site will not be spared. We have yet to hear of contingency plans for dealing with the animals, the effluent ponds, etc. when storms bring driving rains and winds.

To State officials: The Hawaii State Constitution, Article 11, Section 1, directs government officials to "conserve and protect Hawaii's natural beauty and all natural resources" for current and future residents. If ever there was a time that you were being called upon to fulfill your obligation to protect the land and its people, it's NOW. A study of the facts and potential risks will lead you to an inevitable conclusion: HDF's dairy will result in one of the largest environmental, cultural, historical, social, health and economic disasters in Hawaii's history. Any conclusion to the contrary would be one based on denial of the facts.

Sincerely,

Ellen R. Ebata

Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The

management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaula Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luuluaie Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kāua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kāua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kāua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kāua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural

Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the

property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawaii's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kauai but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila melanogaster*, the only Kauai species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation Koa-ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawaii for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kauai and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōloa and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plisch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$6,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered

volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well

water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs

from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāulepū Valley. The dense canopy along the makai end of Waipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

RE: COMMENT ON HAWAII DAIRY FARM'S ENVIRONMENTAL IMPACT STATEMENT PREPARATION
NOTICE, DATED JANUARY 2015.

Dear Ms. McIntyre,

My husband and I have many concerns regarding this proposed Hawai'i Dairy Farm (HDF) in Maha'ulepu on Kaua'i. We have lived in our home in the Bay View House Lots of Poipu Kai, just adjacent to the Grand Hyatt Resort and Spa, for over 17 years. It had long been a dream of ours to live here and enjoy the beauty and peace that this area offered. Now that we are about to retire and realize that dream, along comes (HDF). Even without (HDF) completed we are suffering financial loss on our property investment. As much as \$500,000.00 already and not a single cow in place yet. Just that fact that this project could come to fruition we have lost THAT much value. We have been told that if completed our total value would go down by at least 50%. That's one heck of a hit! These are our selfish reasons for not wanting HDF in our area, following are all the other reasons this just does not make any sense.

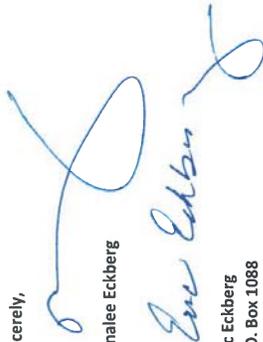

The environment in Maha'ulepu cannot handle the dairy. The resources, our wells, cannot handle the contamination that will come with that much waste. The airborne fumes from the waste (urine and solid), the flies will be horrible and we are down wind most of the time. The soil will not handle this and will then go on to contaminate not just the land but the ocean and marine environment. We fish out there and feed our families, we enjoy the beach and marine life, Hawaiian Monk Seals frequent the beaches of Maha'ulepu, and of give birth and raise their pups there. Hawaiian Monk Seals are on the Endangered List and are the most endangered marine mammal in the United States. As an endemic species of the Hawaiian Islands they feed and breed in the waters, sleep on our beaches. Maha'ulepu is one of their habitat and would be forever ruined.

Our drinking water wells are located adjacent to these effluent ponds and stand to become contaminated forever. Where will we get our drinking water? And speaking of water, where will this 3 million gallons of water they need per day come from? The water from the mountains that collects in Waia Reservoir belongs to all of us and is not for sale to HDF by their landlord. What about flooding, such as happened in 2006? The whole valley out there was under water and they were spilling overflow from Waia that ran to Maha'ulepu. What will happen to their containment ponds where we have rains like that?

We could go on and on why all this does not make sense to place a dairy in such a sensitive area, we have to consider the cultural significance of this area also before it's too late!

I hope these and all the other factors involved will be carefully weighed in the decision made regarding HDF. We are AGAINST this plan. We do not want to see the south shore of Kauai ruined forever. Too many people's lives depend on the economy here and the whole island will suffer a loss in tourism if no one wants to come to Poipu.

Sincerely,

Ronalee Eckberg

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Ronalee and Eric Eckberg:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP), published January 23, 2015, described the proposed pasture-based rotational grazing system

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use: the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mohs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the sebacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhā‘ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West/Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kauai, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data

the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kallhi Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Luualalei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due

to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Niihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Platch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of

approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were

conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kaiāhehe districts), water use in 2035 is projected to be 3.24 MGD, an

increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has

completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter

periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

Attention: Jeff Overton.

RE: Hawaii Dairy Farm (Kauai) - EIS Process

Dear Mr. Overton,

Please find attached my letter with our questions and concerns that should be addressed in the EIS Process for the Hawaii Dairy Farm being proposed on Kauai.

Please let us know if you have any questions.

Thanks in advance.

RE: Hawaii Dairy Farm Environmental Impact Study for operations on Kauai.

My husband and I own a small condo in the Poipu Area and we will be retiring to the beautiful island of Kauai within the next 3 years.

We were very surprised to hear that Hawaii Dairy Farms, LLC is proposing an Industrial Dairy Farm at Maha'ulepu on Kauai with a herd of up to 2000 cows.

We are very happy that there is an Environmental Impact Study being completed but we have many concerns and questions.

My mother was raised in a dairy farming family. My grandparents were dairy farmers and a number of generations before them were as well. They all used "sustainable" and "grass fed" farming practices. My cousins continued the family dairy farming up until just recently.

My family's farm consisted of 100 acres with a total of 25-30 humanely treated adult purebred Holstein cows. They grazed daily in the summer, spring and fall on 10 – 20 acre pastures in a rotational manner to preserve the soil. The land was also used to grow all of the feed required for the animals. They ate only food grown on the land within the 100 acres. Crops (no corn) were grown and stored for winterfeed and to augment feed when they arrived in the barn for milking twice a day. This was and is sustainable grass-fed dairy farming.

HDF is proposing a "Grass Fed" Dairy with cows grazing on 500 acres of land that is within 4/5th of a mile of the Pacific Ocean at Maha'ulepu. They plan to start production with 699 cows and then move to 2000 cows over time. In HDF's proposal at start-up they will have 115 cows in each 4 acres of paddock area per day and at full production 330 cows on each of these paddocks.

500 acres sounds like a lot of land to graze 699-2000 cows on, but basically it means that during the start-up phase 7 cows would be grazing and defecating on 10,000 square feet of "pasture", the size of a standard house lot. At full production it would mean that at least 17 cows would graze and defecate on the same area.

According to the EPA a dairy cow defecates at least 120 pounds of wet

manure every day. In their Waste Management Plan, page 42, HDF reports that they anticipate their dairy cows will each weigh 1,200 pounds and produce 143 pounds of wet manure per cow daily. Using HDF's own waste expectations, at full production HDF's 2,000 cows would produce 2,648 pounds of wet manure on a 10,000 square foot area every day! Imagine having more than one ton of manure added to your lot daily. My husband and I live in a standard house lot of about 10,000 square feet. As I write this and look out my window and try to understand the impact of the concentrated rotational dairy proposed by HDF, I can't imagine anything left of my yard after 17 cows graze, defecate and urinate for even one day. How is HDF going to handle all this manure? How will they keep it from run-off into the wells, streams and ocean? This must be addressed in the EIS.

This manure is not just manure, it is filled with the drugs that the modern farming practices give to these animals such as growth hormones and antibiotics - these will be part of the run-off so how will this affect humans, animals, birds and fish both on land and in the ocean? This too much be addressed in the EIS.

According to HDF, the cows rotate through the grazing paddocks, returning to the pasture paddocks first grazed every 18 days. Not only will the grass be unlikely to re-generate in that short an interval but the manure will still be wet and likely contribute to hoof rot when trampled by the returning herd. This needs to be addressed in the EIS.

The dense grazing will not only sicken the cows, there is also a very real risk to the public's health. There were cases of E.coli in 2006 that were caused by spinach contaminated by feces from cattle nearby. There were 3 deaths and many were sickened. With all the rain on Kauai won't there be a risk of contamination just by run-off? Will the flies carry disease to our food or any containers we eat from? These need to be addressed in the EIS.

What about the chemicals that will be in use to clean the cows and the milking structure and other facilities on-site? This needs to be addressed in the EIS.

I know they use iodine to wash cow udders. When that gets into the run-off who or what does that harm? This too needs to be addressed in the EIS.

What about large animal vets? Are there enough on the island to make

sure these animals are healthy as they need to be examined on a regular basis? This needs to be addressed in the EIS.

In Industrial Farming a cow has only a 5 year life expectancy. Where will all the deceased animals be disposed if they cannot be used for hamburger meat? Could this be another possible contaminate? This needs to be addressed in the EIS.

HDF will have to bring in additional feed for these animals. From where will this additional feed come? I know that there will be an opportunity for farmers on-island to grow crops but what if that does not happen. When additional feed is brought in from other areas what pests, or other contaminants will be introduced to the environment that could cause disease to the plant, animal and human life on the island? This also needs to be addressed in the EIS.

In the Poipu area, we have wildlife that is already protected like the Monk Seal and the Sea Turtle. We also have a tremendous number of fish species living on the reefs on the island. Will these animals and fish or the reefs be harmed from the run-off? This needs to be addressed in the EIS.

My husband and I rent our home at this time and are responsible for collecting over \$13K into the GET and TAT per year. If you multiply that by the number of other vacation rentals in the area it represents a large amount of lost revenue to the State of Hawaii if the tourists stop coming due to odor and flies. Will this possible impact to the state taxes be addressed in the EIS?

Please ensure that the EIS for this project is being done fairly and based on facts that will ensure that the Poipu Coastline will not be negatively impacted.

Thank you for your consideration.

Dear Ms. McIntyre,

Please find attached our PDF file with questions regarding the Industrial Dairy Farm on Kauai (Hawaii Dairy Farms) EIS process.

Please feel free to contact us if you have any questions.

Please let me know that you have received this letter.

Thank you in advance.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Beverley and Joseph Ellul:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and

irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its

present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report, completed in April, 2016 by Plascch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect impacts, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk

Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface

Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Haupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Russell Faraldi:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system

- 1) With the area soil being over lava rock, a very porous material with caverns and tubes how can the dairy negate any contaminants such as the build up of phosphates, chemicals from going to the ocean? And how will the pollution be monitored
- 2) With the amount of cows daily on each "pad"/section rotating over time – what is the assurance that the grass will grow in a timely manner to absorb the urine and phosphates? Seems like there is not enough time between in the rotation of animals through the paddock system to insure the ground and grass are stable?
- 3) What will be the program, on part of the dairy to deal with any stray animals that come onto the property? Is there a protocol? What is it?
- 4) Will the cemetery on the property for the cows be treated with any natural or chemical compounds? Or is it all natural decomposition? Also this same area is near the petroglyphs and Hawaiian worship sites. Will there be any impact? Short and long term? Please define.
- 5) What impacts short and long term might any and all ground run off (intentional or non intentional disaster size) have on the ocean, shoreline and reefs in the area? If they are found to have long-term effects will the dairy consider changing the area on the Island where the dairy is being placed?
- 6) Is the dairy willing to shut down if any problems to the environment are found? Are they willing to put the surrounding environment first?
- 7) What is the dairy's plan if in fact local homeowner property values are negatively impacted by their development?
- 8) Is there a contingency program if the project is allowed to move forward and fails? Please outline in detail how the Dairy plans to restore the environment to its original state as how they found the land.
- 9) Current plan is to start with 699 cows and grow to 3,000. If the impact of these herds is overpowering to the environment in its ill effects, what would the impact be if the amount of animals were reduced by 25% - 50% - 75% Please define.
- 10) What impact might the dairy have on all natural plant life in the area?
- 11) What would the impact on the local animals/insects/life forms in the area?

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the sebacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kāua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kāua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kāua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional

capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kāua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kāua'i may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject

property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specific areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

INVERTEBRATE SPECIES: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāʻulepū area, as well as the parasites and predators on site that control those species. Fieldwork was conducted during September 15-16, 2014. The entire study is included in Draft Environmental Impact Statement (EIS) as Appendix B.

CAVE AND LAVA TUBE INVERTEBRATES

There are no known caves or lava tubes found at or adjacent to the dairy farm property. The Kōloa Lava Tube System, which provides habitat for two endemic cave species, the Kauaʻi Cave Wolf Spider and the Kauaʻi Cave amphipod, is located several miles away from the dairy farm property. Both invertebrates are listed as endangered under the U.S. Endangered Species Act. Not all caves in the Kōloa area contain these invertebrates, as many do not contain the optimal climatological conditions required by these organisms. Neither the botanical and faunal survey nor the invertebrate survey revealed any evidence of lava tubes or caves on the property, and no such features have been reported for the area near the Hawaiʻi Dairy Farms (HDF) site. Thus no cave invertebrate species will be affected by the dairy farm.

INTRODUCED PREDATOR INSECTS

An invertebrate study of manure-associated insects was conducted for the Draft EIS. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently present at the HDF site. Pest insects such as flies can negatively impact livestock

health and production, and are therefore actively managed to prevent stress and loss of productivity at dairy operations.

At the HDF site, two common flies were identified: the stable fly and the horn fly. Both of these flies are widespread throughout the Hawaiian Islands. The greenbottle fly was reared from manure taken back to a laboratory following the field survey. Additionally, flies known to exist on Kauaʻi but not seen at the HDF site during the survey were identified and include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations.

In response to cattle-related insect pests, numerous species known to compete with the pests were introduced to Hawaiʻi between 1898 and 1982. Twenty species of predators and competitors to the horn fly were successfully established during that period. Cattle egrets break up dung patties while searching for prey, and were introduced to Hawaiʻi in the late 1950s to control cattle-associated insects. Extensive introduction of dung beetle species resulted in 14 dung beetle species becoming established on Kauaʻi.

A healthy population of dung beetles can bury a dung pat in one to three days, which disrupts reproduction of flies such as the stable fly and horn fly. The stable fly requires approximately 21 days within the dung patty for the immature life stage (egg to pupa) to survive; the horn fly takes 10 to 20 days from egg to adult. Incorporation of the manure into the soil profile by dung beetles removes the habitat these flies require to complete their lifecycle. Research shows that 95 percent fewer horn flies emerged from dung patties containing a dung beetle species that has been identified at the HDF site. Proven control methods for the stable fly include parasitic micro-wasps and spreading out manure.

Among the invertebrates previously introduced to Hawaiʻi to combat livestock-related flies are extremely tiny parasitic wasps that prey on various fly species. The adult wasps could be described as the size of gnat. Using an ovipositor – described by lay people as a “stinger” – the female lays eggs in the larvae or pupa of flies. The male wasp has no such “stinger”. See Draft EIS Section 4.11 for a photo providing scale for these tiny, non-stinging wasps.

To minimize potential establishment of pest flies or other insects, food waste generated during the construction phase will be bagged, covered, contained and disposed of in order to limit possible breeding habitat for flies. Inspections of building materials for ants or other insects will be conducted to prevent introduction of new pests to the HDF site. Short-term controls, including mechanical methods (e.g. sticky tapes or ribbons in the milking parlor, or traps with or without attractants) and chemical methods may be used to prevent short-term spikes in pest populations.

Insecticides and herbicides are non-discriminatory and kill beneficial as well as pest insects. Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Should chemical control be needed for short-term spikes in pest populations, application would be by those qualified, and in accordance with regulatory labeling requirements. HDF will implement long-term

integrated pest management, which utilizes knowledge of the ancient food web among species by disrupting the manure habitat required to complete the fly life cycle. HDF and other ranchers on Kaua'i may choose to engage with the State Department of Agriculture to translocate dung beetle species already introduced on Kaua'i to Māhā'ulepū and other areas where manure-related flies may be a problem.

IMPACT OF SPRAYS ON BEES

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Honey bees are an essential part of any agricultural ecosystem, and were observed on site during the invertebrate species survey. Pesticides and herbicides can reduce populations of beneficial insects, which is why HDF will utilize an integrated pest management approach.

It is expected that honey bees will visit water sources set up for the HDF herd. Preventative measures will be built into any open water source to prevent bees from being trapped, and HDF will contact local beekeepers for advice regarding any bees or bee colonies encountered on site. Safe application practices for any unavoidable herbicide or pesticide will be utilized in order to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself, a local beekeeper will be contacted for advice and removal.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and

indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa

series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF

established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and

prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

Russell Faraldi
May 26, 2016
Page 14 of 14

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

RE: EIS – Hawaii Dairy Farm

I am writing to ask about several concerns to be evaluated as part of the EIS to the Hawaii Farms Dairy.

My first concern is the lack of objectivity of Group 70 International conducting an EIS – specifically on waste management since Group 70 International created the waste management process. An independent environmental engineering firm should be evaluating the plan and any mitigations. There is certainly a conflict of interest having the developer critique its own plan.

Second, there will be a substantial degradation to the entire Mahaulepu area with a high density herd. For years, local families have been allowed to hike to what is commonly known as "Hidden Beach." This has a spectacular view along the coast line and leads to a secluded beach where many visitors and locals enjoy a quiet day.

Additionally, there are many family traditions of camping at Mahaulepu beach during holidays. All of these activities and way of life will be impacted by gated, fenced areas as well as increase in odor, biting flies, and potential run-off. The dairy insists the feed lot will be zero waste. I am not convinced. The plan to liquify and spray adjacent fields as a "nutrient fertilizer" will either run off during heavy rains or seep into the ground. Such seepage is likely to reach the water table. These "sprayed" fields are as close as 750 yards from the Koloa water well and nitrate pollution to the water via contamination to the water table is a highly likely scenario as evidenced in other states recently.

Third, there have been no reports on how to mitigate biting flies. An entomologist sent Mayor Carvalho an open letter about the typical 5-mile range of such biting flies and how the flight pattern is likely in swarms. Anyone with a pond or pool will have to contend with swarms of flies which can migrate as far as five miles. This would fully impact all outdoor activities as far as Spouting Horn. All resorts such as the Hyatt, Sheraton, Koloa Landing and shopping at Poipu Village, Kukui'ula, and Spouting Horn would be affected. The National Tropical Botanical Gardens are also within the 5-mile zone of migrating flies. Quality of life would be adversely affected; the economy would also be adversely affected as the shopping areas are also outdoors. This entire issue has not been addressed.

A fourth issue is that of irrigation. Recently the State District Court ruled that a private enterprise Kauai Springs did not have rights to the spring water for commercial purposes. Grove Farm has entered into an agreement to supply water from the Waia reservoir which reverted water rights back to Hawaiian rights after the closure of the Koloa Sugar Mill. Access to the water for use to liquify all the solid waste is using a water

Hearts4Kauai

source for commercial purposes. Should the legal defense through Office of Hawaiian Affairs retain rights to the water, what source of water is proposed for the dairy?

Lastly, I personally own a home in Poipu. I am less than a mile from the The Grand Hyatt. I have a fish pond in my yard. My neighborhood is only about 2 miles downwind from the proposed site. Having grown up in Colorado and having been around many cattle operations, I am all too familiar with both the odor and fly problem affiliated with such large scale operations. The proposed site for the dairy operation is too close to some of the most coveted real estate in the country. It is certainly too close to my home.

The concept for the dairy is a theory. The only other example, which HDF points to, is the New Zealand effort. The consequences of the New Zealand effort has been disastrous and well documented. Because I value living in Poipu and consider my home and my access to clean beaches, access to pristine waters off of the Maunalepu coast - integral to my quality of life- I find the proposed site for this large scale dairy to be obviously deficient in analyzing the impact it can have on our lives here.

Maha'u lepu is the wrong location for this project.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Maha'u lepu Road
Kauai, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Cheryl Ann Farrell:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhāulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and

irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the

HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila musaphila*, the only Kaua'i species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōloa and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Platch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would

(EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed, rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD

be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement

Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Mākauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing-agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or

produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu

maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater

and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970 (CAA)*, amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards (SAAQS)* that are as strict or, in some cases more strict than the

panels, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezonning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The

NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of

alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OE6CKAUA1>
Thank you for your participation in the environmental review process.

Sincerely,

Importance: High

All went well until MeadowGold stopped control of nauseous odor and billing files. Waimea Sugar Mill Co. closed operations and Kikiaola Land Co. then owned the Waimea Dairy facility. After Hurricane Iniki, Kikiaola converted the many sugar plantation homes into the Waimea Plantation Cottages. Now came the problem of dairy causing a problem with guests at the Waimea Plantation Cottages; a resort. Kind of like HDF being near the Hyatt Resort, hey?

As a result, Kikiaola evicted MeadowGold, who then moved their dairy to Moloa'a; not to process milk, but to produce milk from the cow herd and send to Honolulu for processing and selling. It was not very long that the local residents of Moloa'a manage to evict MeadowGold, claiming bad odors and dirty run-off that polluted Moloa'a Bay.

This begs the question: "Why not relocate the HDF NOW? There are many parcels that should not result in eventual eviction. Example: Kahili Mountain area. This location is away from residential complainers and business ventures. The special New Zealand grass will flourish there. The higher the elevation, the better the growth. The soil is more porous and less likely to generate major run-offs.

Surely with Mr. Case and his 16,000 acres of former Grove Farm lands, can find a more suitable location that is still "ag" than historical Maha'ulepu. I rest my case.

Alan Faye, Princeville 808-826-7630 Feb 23, 2015

Aloha Bill and staff ~ you may use any or all of my enclosed testimony for TGI.

I'm sending the following to State of Hawaii, HDF@Group70int.com; epo@doh.hawaii.gov. as recommended in today's TGI.

Others too? Council? Mayor? email addresses?

Mahalo,

Alan

Comments re Hawaii Dairy Farms

Does HDF want to consider relocating their eventual 2,000 dairy cow herd NOW, before having to move it later? The history of milking cow dairy's on Kauai is one of relocating here and there until they all moved off the Island of Kauai.

Starting back in around 1905, Mr. HP Faye started the Waimea Dairy as a part of his Waimea Sugar Mill Co. His in-laws had a dairy in Moloa'a prior to his marriage. He suggested to the Lindsay family that they relocate their dairy to Waimea: which they did. Over the many years, Waimea Dairy flourished through the late 1960's when the milk was delivered by milkmen as far as Hanalei on the North Shore of Kauai. The dairy herd was about 278 milking cows.

As a young teenager, through high school, I worked many "dairy" hours. We mulched sugar cane tops and mixed this with pine-apple bran skins that were dried. We even picked keawe-tree beans, as school kids during World War II for ten cents a burlap bag! There was no "milk-tio" feed coming during the War. Keawe-tree beans kept cows cleaner, along with sugar-cane tops and pineapple bran.

Waimea Dairy was always very careful about cleanliness of the cows, pastures and pasteurizing plant. Near the end of 1969, the Faye family faced a required major expense to update the pasteurizing plant. The decision was made to accept an offer from MeadowGold Milk Co. of Honolulu. They would buy the herd, take over operations, and lease the facilities.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4)2-9-003: 001 portion and 006 portion
(4)2-9-001:001 portion

Dear Alan Faye:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations

(CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any posed; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the

cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and

other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds

regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipu region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipu region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to

encompass 19.2 percent of the County population. For the South Kua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling

within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kua'i, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three

times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring

program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5}

is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kauai; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawaii, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Gentlemen,

I have been coming to the Poipu area of Kauai with my family for over 40 years. sixteen years ago I purchased a house at Poipu Kai which I gave to my daughters two years ago. The house is rented when we are not in Hawaii, we pay our fair share of state and local taxes. I am very alarmed by the proposal to start an industrial dairy at Maha'ulepu.

I am very familiar with the down side of dairies. This is not a clean industry, although it is a very profitable one. I frequently drive from my home in Salt Lake City to a second home in Sun Valley, Idaho. I also have a part ownership in a farm, 1700 acres, on the Snake River in the heart of the Idaho dairy industry, Hagerman Idaho. The dairy industry has been a good investment for many including local and state governments. It has not been as friendly to those who live with the constant smell of manure in the air, the flies and other insect pests, the huge tractor trailers delivering hay and food to the

farms, and the piles of manure stored under tarps to allow "natural fermentation and digestion" in the open air. The anaerobic digesters smell the same.

There have been many reports of the health problems associated with the dairies. These vary from the exacerbation of respiratory diseases, to the pollution of the aquifer. Brain damage caused by excess nitrates in human infants has been well documented, as have reproductive problems, and cancer. The attached article, "Cow Country: The Rise of the CAFO in Idaho...the conflicts between people and cattle are increasing" details the problems of large scale dairy production in detail. The response appears to "pay off the injured" and move them out of the plume of polluted air. Our Governor, Butch Otter, carefully switches to blame to the people using nitrogen containing fertilizer. In southern Idaho the dairy industry will probably not be displaced. There is nothing unique about the landscape; any historical artifacts from the original settlers have long since been removed. It is not Maha'ulepu.

The introduction of a commercial dairy operation into Maha'ulepu will cause irreparable damage to the south shore Kauai, its streams, and beaches. The pollution in Waiohale Stream will increase as the waste from 2000 cattle percolates into the water shed. The changes in nitrate and other pollutants will eventually reach the beaches. The flies and the non-native species of wasp that the dairy proposes to use to counter act them will spread from the dairy to Koloa and Poipu. Golfers will get to experience the smell of cow manure. Most importantly for those in government, tourist visits will decrease and property values will drop. Opportunities for employment will decrease. Income from taxes of all kinds will decrease. HDF can walk away from the project if it turns into an environmental disaster leaving the taxpayers of Kauai and Hawaii to pay the clean up bill. There is nothing in the HDF to provide compensation for these losses. Once the soil of Maha'ulepu is contaminated with dairy pollutants including nitrates, the loss will be long term.

The HDF proposal does not address the public health consequences of polluting the aquifer that we all depend on, or the expected rise in respiratory illness that accompany industrial dairies. It does not address the accidental importation of invasive species with the cattle and their food. It does not address the loss of one of the most scenic areas of the island, the down stream consequences of a rainstorm like 2006 which caused one of the dams on the island to fail, or another storm like Iwa or Iniki.

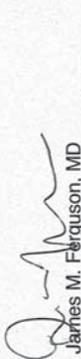

Economically, the upside profitability of the Maha'ulepu dairy is questionable given that the owners of one of the largest dairies in Idaho, Steve Whitesides who boasts in the local Rupert paper that he has 14,000 cattle in his herd, has an industrial dairy operation on the Hamakua Coast 30 miles from Hilo where his Big Island Dairy produces 15,000 gallons of milk a day. Why not 14,000 cattle here too?

Boise Weekly

BOISE WEEKLY Submit your Instagram photo to #BOISEWEEKLY and one photo is selected each week to feature in Boise Weekly

In summary, I think the proposed industrial dairy at Maha'ulepu is a bad idea.

Cow Country: The Rise of the CAFO in Idaho

As mega-dairies and feedlots make up more of Idaho's dairy industry, the conflicts between people and cattle are increasing

By Scott Weaver

On a cool June day, Dean Dimond looked out from his back porch at a field of green wheat bending in the wind. Dimond lives on and farms a patch of land in the Magic Valley just north of Jerome. A mile or so beyond is Minidoka, site of the former Japanese internment camp where the National Park Service is building a memorial.

Dimond is, by any measure, an enormous man, with trying pan-sized hands that engulf yours in a handshake. He makes his living growing hay and corn for the dairies that populate this area where he has lived nearly all his life. It's a good place for this kind of farming. Three counties in the Magic Valley—Jerome, Gooding and Twin Falls—have the highest concentration of dairies in the state.

So you wouldn't expect Dimond—a self-described staunch Republican—to side with a movement to slow and even stop the expansion of large dairies. But as he looks over the field just feet from his back door, the contradiction begins to make sense. Over the last two decades, the vision of a dairy has morphed from an idyllic setting to an industrialized, Henry Ford-like factory—the concentrated animal feeding operation. Under the logic of economies of scale, dairies and feedlots grew into expansive operations able to hold tens of thousands of animals.

The wheat field behind Dimond is not his, though you could toss a rock from the porch into its stalks. It belongs to South View Dairy, which for the last three years has fought to construct a 13,000-head feedlot on 240 acres one mile upwind of Minidoka and next to Dimond's home.

"There are a lot of good dairymen out there," said Dimond. "The dairy industry has been really good for this area. There are some that try to take care of their neighbors. But these guys just wanted to come in and build this mega-facility."

The fight over South View became so contentious that Jerome sheriff deputies used metal-detection wands to search the public for weapons before one hearing. During the hearing, a woman was led by a bailiff from the courtroom after retching to yield the floor to the county commission chairman.

In many ways, South View is emblematic of what former Jerome County Commissioner Diana Obenhauer called a shift in public attitudes about CAFOs in their county.

While the dairy and beef industries are revenue generators for counties and financial livelihoods for the state—Idaho is the fifth-leading producer of milk and dairy products in the nation—there are the physical and environmental landscape are fighting for their property rights and better regulation of operations. And to make their voices heard.

"We all have cows. We all understand them," Dimond said. "But these things need to be located out and away where they can't affect people. These guys came in and wanted to put it right on top of us."

During the 1980s, an exodus of dairies from California reshaped Idaho. By 1997, income from dairy products exceeded those from the state's signature crop, potatoes. The year, dairy outpaced both potatoes and beef. Dairy operators fleeing California's regulations found in Idaho a state with space and a welcoming attitude.

But the boom didn't translate into more dairies. Between 1991 and 2007, the number of dairies dropped from 1,952 to 648. During the same period, the amount of milk produced skyrocketed from just less than 3 billion pounds to 11 billion pounds.

What was once an industry of small farms has become dependent on CAFOs. The average herd size increased from 91 cows in 1991 to 783 in 2007. The decrease in dairies coupled with the increase in herd sizes puts more animals in fewer concentrated areas.

CAFOs' environmental impacts are evident. Putting 1,000-plus cows in a confined space produces an enormous amount of animal waste that often contains high levels of nitrates, pesticides and pharmaceuticals. If not properly handled, it can leach into surface and ground water. According to a 2006 paper in *Environmental Health Perspectives*, this happens all too often:

"Based on available data, generally accepted livestock waste management practices do not adequately or effectively protect water resources from contamination with excessive nutrients, microbial pathogens and pharmaceuticals present in waste."

The Idaho Department of Environmental Quality has found increasingly elevated nitrate levels in areas heavily populated with CAFOs. These levels are caused by fertilizer applications—including spraying of liquid manure onto fields—and "agricultural water can cause brain damage in infants and has been associated with reproductive problems and cancer, according to researchers at Colorado State University.

According to the DEC, nitrate is a concern because more than 95 percent of Idaho's drinking water comes from groundwater. The Magic Valley and its CAFOs sit on the Eastern Snake River Plain, the only source of drinking water for 200,000 people in Southern Idaho.

CAFO Tour

Click to View 11 slides

A 2009 DEQ study of the Springdale area in the Magic Valley found that nitrate concentrations "commonly exceed the maximum contamination level." While the study argued that the "concerning nitrate concentrations" also increased from 1993 to 2001, it didn't mention that "possible sources" include CAFOs and their practices.

However, DEQ cites two ISDA studies in 2003 and 2005 that it says "suggest a connection between agricultural land use and groundwater quality." According to the DEQ, there were roughly 14,000 confined animals within the 22,000 acres of Springdale. According to the 2000 census, Cassia County, where Springdale is located, had a human population of 21,416.

"The ISDA studied [concluded] that nitrate impacts to the shallow aquifer are widespread," the DEQ report stated, "and the leaching of animal waste and use of commercial fertilizers is the likely source of nitrate to ground water."

In 2006, the DEQ found "a statistically significant increasing nitrate trend" in Gooding County, ground zero for dairy CAFOs. A follow-up report in 2009 found that the largest "potential" sources of nitrogen were fertilizer applications (47 percent) and CAFOs (43 percent). The report estimated that dairy cattle produce 2.4 million pounds of nitrogen load a year, more than double the second-leading source, feedlot cattle (983,000 pounds). Like most studies, its recommendations are thread-bare: CAFOs should use "best management practices" to control the amount of nitrogen that reaches the aquifer and springs.

Lee Halper moved to Idaho in 1971, after living in "the fifth and corruptest" of New York City, Boston and New Jersey. In the late '80s, the Ardenma Dairy—the largest dairy complex in the state—moved in over the aquifer that feeds his well. Over the next 25 years, the nitrate levels in his well increased from 1.4 milligrams per liter in 1989 to 7.28 in the fall of 2008. Levels rose as high as 11.02 in 2006. The federal maximum contamination level for nitrate is 10 milligrams per liter.

"There are good CAFO operators and there are bad," Halper said. "Combined with the corruption and ignorance of politicians, this allowance of free reign for 'jobs' is slowly ruining the aquifer, the soil, the roads, the air ... Idaho." CAFOs also degrade air quality. A 2003 DEQ report on the Treasure Valley found that 64 percent of ammonia emissions "come from livestock waste, the largest source. This DEQ study was significant because it contradicted previous environmental impact studies for a proposed 8,000-head dairy CAFO, which ISDA found would have a "minimal" impact on the environment.

If there's one criticism that residents and anti-CAFO activists alike have of ISDA (and there isn't just one), it's that the agency's interests and the interests of the industries it regulates overlap to the point of being indistinguishable at times.

If the word "guilty" did not exist, it would be necessary to invent it to describe Alma Hass. The executive director of Idaho Concerned Area Residents for the Environment is also the woman who was kicked out of the South View hearing.

Alma and her daughter, Shavone, are the heart and brains of ICARE. "I'm in a car with both as Alma exits I-84 just west of Twin Falls and exclaims, 'It's Excrement Alley!'"

That's Alma's nickname for Bob Barton Highway, which runs between the Interstate and the Snake River in the Magic Valley. It's also the prime spot for our "Shit Tour," a drive through an expanse of dairy and beef CAFOs tightly packed into the acreage on the north rim of the Snake River Canyon. Like many in urban areas, my experience with agriculture ends with "Old McDonald." That luscious idea has been tempered with second-hand knowledge: reading Michael Pollan, et al; watching Food, Inc. and various exposés. I expected a certain amount of disgust on the Shit Tour. Even my wildest urban imagination couldn't conjure Excrement Alley.

As we drive by a dairy CAFO, a 4-foot curving berm of cow shit follows along the fence line. Inside are pools of water with a glassy green-brown surface. Liquid shit, Jersey cows stand and lay under the sun. There's nothing green among the cows surrounded by dirt and dust, making it difficult to tell where the earth ends and the shit begins.

After an hour of this, my head begins to ache and my eyes water. It's not even dusk, when the cooling air brings the noxious gases closer to the ground. As she drives, Alma points out piles of manure and waste lagoons—pits where liquid animal waste is collected until it can be sprayed on fields. A cow staggers through the muck, dazed by the sun.

ICARE is part of the coalition that temporarily stopped the proposed South View facility. Neighbors are still waiting on a ruling as to whether the CAFO can begin construction.

ICARE works with citizens and lobbies for better state regulations on CAFOs. Alma argues CAFOs are Idaho's top public-health threat, negatively affecting water, air and soil quality while making life unbearable for those who live near the largest operations.

"I wish I could charter buses and take the senators and representatives on a tour like this," she said. "And have them look me in the eye after and say that these facilities aren't having any impacts."

At the Snake River Canyon, we walk to the north rim. Hundreds of feet below, the Snake River runs turbid. Nothing breaks the surface of the solid green water. We're standing on basalt, a porous rock through which surface water easily finds its way into the ground, the aquifer and, ultimately, the river. Thick strands of algae sway languidly. At a bend, the river is full of them, evidence of the elevated level of nitrate. An Irrigation canal empties from the southern rim, shooting its water down into the Snake.

"That irrigation return line has probably snaked past no less than a dozen CAFOs," says Alma. "There's probably all kinds of stuff in there. You wouldn't want to drink it, swim in it." Just months before, my wife and I took a backpacking trip through Hells Canyon, some 300 miles downriver. A park official warned us not to drink or eat anything out of the Snake, even if we boiled and filtered the water, because of all the CAFO run-off.

These are the macro effects. But living in close proximity to a high concentration of CAFOs comes with its own hazards, some of them due to the nature of the operations. Others are due to the nature of the operators.

Though ISDA is tasked with promoting the dairy and beef industries, it also regulates them, ensuring that dairy products are safe to eat and drink. ISDA is also responsible for regulating the health and environmental impact of operations that in many ways have become more like factories.

"We do have a dual role," said Brian Oakley, ISDA deputy director. "We promote agriculture, but we also regulate. We have to reconcile that in all of our programs. If we don't have a credible regulatory agency, then we can't promote the consumer confidence in those products. We view it not as a distinction between the two, but really one in the same. We're doing both: regulating and promoting."

Most people interviewed for this story don't share Oakley's confidence in ISDA. Diana Obenbauer, the former Jerome County commissioner, said ISDA "neglects" its regulatory responsibilities. "They don't do their job," she said flatly. Dean Diamond goes further.

"The Department of Ag is kind of a worthless organization," he said.

After Diamond complained to ISDA about a CAFO illegally pumping its waste, his name appeared in the letter to the operator, essentially outing him to the industry he depends on to make his living. The ISDA inspector for that region stopped taking Diamond's calls.

ISDA permits and inspects operations, collects fees, issues fines and monitors the environment and approves Orwellian-named documents called Nutrient Management Plans, which detail how each operation will safely hold and dispose of animal waste.

Activists point to these NMPs as proof of the industry's cozy relationship with state regulators. NMPs document the amount of waste CAFOs produce and how they plan to deal with it. Problems with waste containment lead to illegal discharges. But this information is kept secret from the public thanks to a change made during the last legislative session. The Idaho Legislature labeled stats on cow shit "proprietary information," exempt from public disclosure.

When asked what in an NMP could be considered a trade secret, Oakley said, "Well, I don't know. I'm not a feedlot operator, so I'm not qualified to answer that. We just implement that part of the statute."

Some of ISDA's more aggressive critics, like Obenbauer, question whether ISDA is doing its job. The fact that these NMPs are private worries ICARE and others who want to do more. "I don't know if it's necessary whether ISDA is doing its job. It's whether they can trust the agency to look out for the interests of all Idahoans. Hiding waste information behind the veil of 'trade secrets' and some wanting public information requests—ICARE needed a lawyer to review public documents—has eroded trust in ISDA."

Regulating beef and dairy CAFOs can be a dizzying job. If a CAFO is affecting air quality, making everything smell like cow shit, you have to file a complaint with ISDA ... unless it's fugitive dust (actual particles of shit). If it's dust, you call DEQ, if the CAFO is emitting ammonia, DEQ is your regulatory agency, unless it's a beef CAFO. Ammonia emissions aren't subject to a CAFO permit. If a truck accidently dumps manure on your road, ISDA can take care of that, unless the manure came from a beef CAFO, which isn't subject to such strict regulations. If a CAFO discharges waste into stream that then finds its way into another body of surface water, both ISDA and EPA have dual regulatory authority.

Up until May 2009, the EPA had agreements with ISDA and both the beef and dairy industries that let ISDA carry out inspections for both the state and federal agencies. The agreements, called memorandums of understanding, were nationally lauded for being unique programs that eliminated the majority of illegal discharges.

But in 2009, the EPA backed out of both MOUs, worried that its agreement—one that essentially ceded its role of inspecting CAFOs to ISDA—would limit its authority to enforce the Clean Water Act. The EPA was also concerned about the close relationship between industry and ISDA.

"The industry that was supposed to be regulated by the regulatory on those MOUs," Nick Peak of the EPA said. "That was one of the primary concerns."

When the wind picks up in southern Jerome County, life becomes more difficult for Bill Jacob and his family. They are surrounded by three CAFOs in the same square mile and at least 10 within two miles. Dirt, dust and particulate matter—the polite name for pulverized cow shit—are lifted up on the wind and carried to Jacob's house. During the worst times of the year, they have to constantly spray and wash the house to keep the brown clouds from settling.

"The worst is when you get a big storm blowing through. You can literally see a wall of dirt coming. And it's not just dirt."

Jacob's son Kyle, whom he and his wife adopted, died of an asthma attack in March 2008, one of the windiest times of the year.

"We were getting hammered by crap blown off the dairy," he said. "The cause of Kyle's death was listed as 'environmental conditions.' But you know, I can't go out there and say there's a smoking gun."

Jacob said there is an "awful lot of evidence" that the dust from the dairies triggered Kyle's asthma attack. "But there's no way we can ever prove it," he said.

Kyle's 3-year-old half-sister is already starting to show symptoms of asthma.

The Jacobs moved to their home in February 1993. Since then, the dairies have continually expanded, increasing the size of their herds and the by-products—animal waste—which bring their own set of problems.

"When you have such a tremendous supply of organic rotting material, the flies are phenomenal," said Jacob. "It can be horrendous, literally horrendous. We knew there were dairies in the area when we moved in. The problem is, it's getting worse."

Of all the counties that depend on the influx of CAFOs economically, Jerome County has a reputation as being especially dairy-friendly. When the Ted Miller Dairy on S. 500 Road decided to expand, residents near the dairy were notified of an upcoming public hearing where they would have a chance to give testimony about the proposed expansion.

"We were given virtually no notice," he said.

Jacob received his notification at the beginning of June. Jerome County had given them three-weeks notice of the hearing.

To submit written testimony, residents needed to file it and additional paperwork seven days before the hearing. But in order to give the necessary documents—records of past violations, sibling information, correspondence between the dairy and the county commission—residents had to request public documents from DEQ and ISDA, which can take up to 10 days. In this case, the residents against the expansion—roughly 90 percent of the people who live in the area, according to Jacob—had to fight for the documents they needed to show that the Ted Miller Dairy didn't have the resources to handle more cows.

When Jacob got the notice, he called ICARE. Alma and Shavone, lawyer in tow, got the documents the residents needed.

"I give a lot of credit to ICARE," he said. "They pounded a lot of pavement really fast."

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear James & Susan Ferguson:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawaii Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali

James & Susan Ferguson
May 26, 2016
Page 2 of 8

formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed, rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of

groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built

facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to

create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients, from Effluent, Irrigation, and Commercial Fertilizer. Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāhūlepu will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the

Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OE0CKAUAI>

Thank you for your participation in the environmental review process.

RECEIVED

FEB 27 2015

GROUP 70 INTL

As long-time owners of a rental condo in Poipu, Kauai we are very concerned about the proposed Hawaii'i Dairy Farm in Māhā'ulepū Valley. This type of operation is not compatible with the condos, homes, hotels or environment of the Poipu area. A dairy of this size, this close to a developed area, will inevitably have a negative economic impact on us, our neighbors and surrounding businesses. We and our guests enjoy the many outdoor activities in the Māhā'ulepū area. Why would our guests want to go to a beach near a dairy operation? Why would people come to a resort with a major dairy operation nearby? They won't, and with the wide use of social media, word will spread that Poipu is now a less desirable destination. We will lose money – will the dairy compensate our losses and how would we prove that impact? It will also have an environmental impact on the Māhā'ulepū Valley waterways, groundwater, beaches and ocean. Even the best farming practices cannot make a dairy operation of the proposed size into a benign project. There are countless examples of dairy farms polluting their nearby environments through runoff, air-borne smells and leaching. A commercial operation would also bring increased truck traffic. The EIS must take all these factors into consideration. This is the wrong site for such a project. Please stop this disastrous project for the good of all Kauai.

Sincerely,

Collin Fleming & Kim Factor

Dear Collin Fleming & Kim Factor:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kauai'i to produce fresh, locally available nutritious milk for Hawaii'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S.

Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The

management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Platch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000

annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The

aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water

quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi

Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural

fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 3,851.0 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water

masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

TRAFFIC. The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site is via Māhā'ulepū Road, a two-way, two-lane road, which is accessible from Kōloa Road (Highway 530) via Ala Kinoiki Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from Māhā'ulepū Road.

Roadways in the project area operate smoothly with no periods of heavy traffic. On average, traffic in the region is much lower than urban areas in the state due to the low population of Kaua'i and rural agricultural demographics of the south Kaua'i area and Māhā'ulepū. Traffic on Māhā'ulepū Road consists of agricultural vehicles, residential and resort visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhā'ulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoiki Road and Kōloa Road was 8,000 and 6,500 cars daily; HDF-related traffic would add less than one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoiki Road and Kōloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have a minimal effect on traffic conditions at County

roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawai'i Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient

air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM_{10} is 2.01 $\mu\text{g}/\text{m}^3$, well below the State standard of 150 $\mu\text{g}/\text{m}^3$. The estimated concentration for $PM_{2.5}$ is 0.23 $\mu\text{g}/\text{m}^3$, well below the Federal standard of 35 $\mu\text{g}/\text{m}^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those

of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2), grow

- local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
 - One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
 - The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
 - Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTL

RESPONSE TO HAWAII DAIRY FARM'S ENVIRONMENTAL IMPACT STATEMENT
PREPARATION NOTICE

Dear Sir, Ma'am,

It is a very bad idea to have an Industrial Dairy at Mahaulepu Valley. The imminent damage to this unique pristine island physically, culturally, and economically cannot help but will be disastrous and irreversible. Although I support farming and small dairy farms on the island, I do not support an Industrial Dairy with unprecedented number of cows per grazing acre in a culturally sensitive, unique and beautiful Oceanside Valley.

It is also my understanding that neither Grove Farm nor the State Department of Health are willing to post a sign warning families of small children about the known bacterial content in the stream coming from the proposed HDF farm site that emerges near the mouth of the cave and forms a fresh water pool on the soft sandy beach at Mahaulepu. That warm pool with the stream running through it to the ocean is a favorite playground for island children and visitors. I consider that to be egregiously irresponsible by these stewards of our island.

In my reading of the EISPN, it does not, but should include a detailed study of the known pollution levels with identification of causes and methods to eradicate. No further development should proceed until HDF can prove to the public that the contamination has been eliminated and will not recur with any activity they propose. If they are not able to do this with any degree of scientific proof (not unsubstantiated promises), then Grove Farm and HDF must be directed by our Department of Health to relocate HDF proposed animal feed operation to a safer environmental location without the obvious risks occurring at Mahaulepu. Please consider other more isolated locations for the sake of all Kauaians.

The watershed and hydrologic drainage from the proposed farm site, both above and below ground must be thoroughly assessed by an environmental engineering firm. Nothing less should be acceptable by HDF or the Department of Health. I will anxiously await and watch for the results of that study.

The threat of this dairy farm polluting, the streams, the ocean/beaches along the south shore, our three water wells is very real. The Manure in the water, with the direction of the wind and ocean stream, will be trapped in the Children's Swimming Area of Poipu Beach Park (the best toddler ocean pool in Hawaii which is part of our Famous Poipu Beach, voted the #1 beach in the United States and always in the top ten beaches). The EIS must include a detailed study of the probable massive fly population that will develop in the warm moist climate in Mahaulepu and show proof that the fly population can be sufficiently abated to ensure visitors to Mahaulepu and the south shore will not be sickened from bites from these flies.

(over)

As any entomologist will confirm, one fly lays a minimum of 300 eggs and they prefer warm wet manure. The types that develop in manure are horn flies, stable flies, deer flies and horseflies; all piercing sucking flies that exist on blood. Our frequent rains will greatly increase the proliferation and these insects can fly up to 4 miles from the HDF site. Within a few months, there will be billions of flies. The EIS must offer proof that this will not happen. Please hire the best environmental entomologist available for your study. We also need to know the facts as to how the HDF will control run off. Gravity operates at even a small pitch (especially over clay soil) and this land is only 65 feet above sea level. Although the proposed sloping the land to the ditches could encourage control of the run off, you are really just passing it to the Waipili stream which runs to the ocean. In a few years it will have polluted all the beaches along the south shore. In addition, how you will reduce the Nitrates in the water and the methane gas contribution to our fragile Ozone layer.

The overall probable long-term impact of allowing HDF to go into production is as follows:

- There will be no more eating on our lanais, thriving outdoor restaurants or picnics on the beach.
- Bankruptcy of restaurants, businesses and condos will follow.
- Unemployment will be rampant as the economy of the entire island gradually dies from loss of jobs related to the loss of our profitable Visitor Industry.

In return HDF will provide maybe a dozen "filthy jobs". Certainly that is not an acceptable trade off.

As I stated earlier, HDF is a bad idea for the proposed Mahaulepu location and I'm an objectively conducted EIS will bear that out.

Sincerely,

Karl Forer
1939 Haelukama St.
Lihue, HI 96766

healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source

of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila musaphilia*, the only Kaua'i species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of

manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōhā-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōhā and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasc Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be

produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōhā area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōhā series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the

unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow

comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kāihāeo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hatupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable

to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and

a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator

bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

GREENHOUSE GASSES: Draft Environmental Impact Statement (EIS) Sections 4.19 and 4.26 address the potential for greenhouse gas emissions by Hawai'i Dairy Farms (HDF). Estimates of GHG emission rates from a pasture-based dairy, including methane and nitrous oxide, were calculated using the 2006 Intergovernmental Panel on Climate Change (IPCC) Guidelines for National Greenhouse Gas Inventories. Parameters for Oceanic dairy cattle in warm climates were selected as most applicable to conditions at HDF. Long-term operational impacts were modeled using the IPCC guidelines and conversions, and estimated the emissions potential for GHG at the dairy at the committed herd size of 699 milking cows to be 2,693 CO₂e metric tons per year. This equates to roughly 1.02 percent of the utility power generation sector on Kauai in 2013, which does not include vehicle emissions and other GHG emitters on the island.

Potential GHG emissions for HDF at the contemplated herd size of up to 2,000 milking cows was modeled as described in Section 4.19.3 using the IPCC guidelines and conversions. The estimated total of 7,702 CO₂e metric tons per year (8,490 tons) is 5,009 CO₂e metric tons (5,521 tons) greater than the committed herd size of 699 milking cows. This equates to an increase equivalent to 1.91 percent of GHG produced on Kauai for power generation by the utility in 2013 (KIUC, 2014). Power generation does not include vehicle emissions and other GHG emitters on the island.

While the presence of cows may increase GHG, a long-term beneficial impact of the grazing fields is the sequestration of carbon as CO₂ captured by the process of photosynthesis by the grass. According to recent studies in the Soil Science Society of America Journal, converting formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, which enhances soil quality, grass production, and has the potential to offset up to one-third the annual increase in CO₂ production of an area.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Comments on Preparation Notice of Draft Environmental Impact Statement (EIS) for Hawaii Dairy Farms - Proposed Dairy Operation

Dear Ms. McInyre and Mr. Overton,

Because Mahaulepu is one of the few open spaces in the Poipu area and is beloved by both residents and visitors it is important that there be very strict monitoring so that the dairy has very little to no impact on the area.

1. Percolation studies of the soil on all parts of the dairy land - both before and after the cows come. How and when will these studies be done and how transmitted to the public?
1. If the studies in #1 show any increase in pollution to the stream or ocean, exactly what action will be taken by the company? Will the number of cows be cut or not increased? What are the guidelines for cutting the herd size or not increasing it?
1. Exactly what kind of road development will take place for shipping out milk and shipping in feed, equipment and workers?
1. Is there enough shipping to send all the milk to Oahu for processing? What plans are there for increasing shipping? Have the shipping companies enough capacity? Please quote their responses.
1. What present walking trails will be impacted and what are plans to continue those trails or make others?
1. There is a lot of population near the dairy site. Exactly what will be done to ensure that there is minimal to no impact on this population: this includes wind monitoring before and after cows come, distance cow smells will be felt, noise involved in the operation and air quality? Show studies both before and after the cows come and make the results available to the public.

1. Impact of runoff. Studies now and after cows come. What will be done and is there any impact?
1. If the dairy fails what will be the left over impact on soil quality? What is that quality before and after cows come and after the dairy shuts down? Will there be money set aside to care of all detriments if the dairy goes out of business?
1. What is the EXACT plan for selling the milk and to whom? What if cost of milk continues to fall? How low can it go for the company to still make a profit? Take into account the cost of transportation, containers, feed and all monitoring that will be necessary and how will the results be transmitted to the public?
1. Will the dairy use of water reduce the water needed by farmers and for drinking?
1. Exactly how many additional electric poles will be needed for electricity to the site or will the wires be put underground?
1. Exactly where will the buildings (milking parlor, offices, etc.) be situated so they do not show from the shore and walking paths?
1. Any small impacts (noise, smell, sight, etc.) should be considered as a whole to assess the total impacts. How will you do this monitoring before and after the cows come and transmit it to the public?

I would like to be listed as a consultant person for the draft EIS.

Sincerely,

Margery Freeman

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ūlepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

NOISE: Existing noise conditions of the project site and the surrounding Māhā'ūlepū valley area are evaluated in the Draft Environmental Impact Statement (EIS), along with anticipated short-term and long-term noise conditions associated with the dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai'i Department of Health (DOH) rules use the A-weighting sound network (dBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes. The Hawai'i Dairy Farms (HDF) site in Māhā'ūlepū Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition, occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 78 decibels or that cost a total of more than \$250,000. Mitigation measures to minimize construction noise will

include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plach Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the

contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the

ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kāihāeo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hatupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore

increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipoli Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

recreation waters at the terminus of Waipoli Ditch, or of surface waters in the Māhā'ulepū Surface Water-Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waipoli Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waipoli Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waipoli Ditch Sanitary Survey, Kaula, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waipoli ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waipoli Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

TRAFFIC. The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site is via Māhā'ulepū Road, a two-way, two-lane road, which is accessible from Kōloa Road (Highway 530) via Ala Kinoiki Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from Māhā'ulepū Road.

Roadways in the project area operate smoothly with no periods of heavy traffic. On average, traffic in the region is much lower than urban areas in the state due to the low population of Kaua'i and rural agricultural demographics of the south Kaua'i area and Māhā'ulepū. Traffic on Māhā'ulepū Road consists of agricultural vehicles, residential and resort visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhā'ulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoiki Road and Kōloa Road was 8,000 and 6,500 cars daily; HDF-related traffic would add less than one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoiki Road and Kōloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawai'i Department of Transportation and County requirements. Delivery trucks and milk tanker trucks

will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5}

is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Re: EISP-N. Hawaii Dairy Farm

Maha'ulepu. The place name evokes fondest memories. Since discovering this pristine spot on a guided walk with Malama Maha'ulepu President, Beryl Blanch in 2008, Kaula's last undeveloped watershed has been "the" special hike we've taken with family and friends. Everyone recognizes immediately its spectacular beauty; preserving its rare character is naturally a topic of our conversations.

Now we're learning about Wai'opili Stream pollutants from Dr. Carl Berg's water tests, confirmed and retesting done currently by Hawaii State Dept of Health. And that Hawaii Dairy Farms (HDF) wants to install a dairy farm on this land of not only priceless beauty but of historically significant archeological sites — heiau, burial dunes, petroglyphs, tide-pools, salt beds — and cultural practices performed to this day. Several visits to Makauwahi Cave Reserve greatly inspires Maha'ulepu's protection.

Kyle Datta, general partner Ulupono Initiative states the dairy's purpose is "to produce fresh, local milk for families across Hawaii State at prices everyone can afford" and that the dairy "will strengthen the ability of the agricultural sector to continue to provide meaningful jobs and valuable economic support for Kaula i." Highly debatable.

In my opinion, the strengths of Kaula i are our Environment—clean Air, clean Water, clean Land, clean Ocean—and, the Spirit of our Citizenry. Environmental degradation continually takes place from chemical sprays, fuels, exhaust, landfills, poor practices such as discarding plastics and nets in the sea, the presence of people and animals, and so forth.

I oppose HDF's dairy plan. Collective manure calculations, clay soils allowing manure/urine run-off into this vital land and surrounding seas are recipes for disaster. Hawaii State Dept of Health should fear well-water contamination. Dr. Katherine Muzik, Marine Biologist, told me her dive in waters off Maha'ulepu revealed a gorgeous living coral, large as a car. How long will our land and seas sustain viability with constant cow mess run-off? We cannot keep compromising our environment with unchecked development after unchecked development.

HDF plans copious water withdrawals from the Waita Reservoir. That must not be allowed to happen. Water belongs to Everyone per our Hawaii State Supreme Court.

And the odoriferous stink! No one wants to smell a dairy farm, neither residents nor visitors. Think reduced residential and business property values. Think residents selling (if they can) and leaving; think visitors flying elsewhere.

Flies. They always accompany cows. HDF plans wasp importation, a foolish if not absurd idea. Dealing with a negative with another negative results in two (2) negatives. Example: importation of guinea grass to feed earlier livestock has resulted in island-wide invasion of that grass.

What about the plan to ship all the milk to Oahu for pasteurization and bottling and distribution? I feel that is a very unsustainable practices plan. Milk must leave in expensive refrigerated units, in all likelihood never to show up on Kaula i Island again.

I recall Amy Hennessey, HDF spokesperson, saying there may be as many as 15 jobs created with the dairy in place. While I don't pooh-pooh 15 jobs, the resulting environmental degradation level by HDF that weighs in would in all likelihood be tragic. The curtailment/loss of hundreds of visitor industry jobs may be at stake. Grand Hyatt, Po'ipu, itself employs 800+ Kaula i residents.

It isn't Environmentally sound and it isn't Sustainable, therefore I urge NO DAIRY at Maha'ulepu.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Sharon Goodwin:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-

Sharon Goodwin
May 26, 2016
Page 2 of 11

Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered projects, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenhouse fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the

HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila musaphilia*, the only Kauai species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ohi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kauai and those species already in Maha'ulepu Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōka-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kinoiki Road between Kōka and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Placch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would

be expected to average about 16 jobs on Kauai, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kauai.

The HDF project would contribute to diversification of Kauai's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kauai, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kauai, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kauai and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement

(EIS) sections 4.16, 4.17, 4.22, and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD

produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauai region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu

Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaula Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kaula, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or

maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation, and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater

and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the

NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of

Sharon Goodwin
May 26, 2016
Page 11 of 11

panels, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: Questions and Concerns Re EIS for HDF

Group 70 International Inc.
Attn:HDF a Project
Honolulu, HI 96813
Hawaii State Dept of Health
Environmental Planning Office
Honolulu, HI. 96914

To whom it may concern:

MAHA'ULEPU is a living museum with its diverse ecologies, endangered species and cultural sites. It is imperative that the E.I.S. process acknowledges that there may be many more discoveries yet to be unveiled. How can these be protected and managed? Recent findings by HDF of petroglyphs rocks and heiau are examples of this.

Please address protection issues for any existing cultural artifacts such as petroglyph rocks and heiau and the ability of the Native practitioners to be able to continue their practices.

The type of soil in the valley is particularly suited for Kalo cultivation. Surely the run off from the proposed Dairy will impact the existing soil preventing production of Kalo or anything else in the future? How will run off affect the quality of the soil and the Former Salt Pans which can be restored?

Will there be percolation tests conducted? Ground water and surface water contamination is of major concern as the high water table is down from the dairy site.

The valley floor is subject to flooding the possible impacts of run off, spillage etc into the aquifer and ocean must be determined. Waiopi stream cannot afford more pollution and the impacts on the health of beach goers, as well as the ocean, reefs, fishing and endangered sea creatures could be dire. How is this being assessed?

Will a hydrology study be conducted to include both Maha'ulepu and Pa'a?

How will the odors and flies be controlled? Using chemicals and introducing other species to ameliorate flies could result in more environmental and pollution problems.

There are endangered species existing in the valley itself how will these be protected?

The flies, odor and degradation of the beaches would have severe economic and health impacts on the South shore community and visitor industry. Already there are less visitor bookings for 2016 due to the possible Dairy. There are thousands of people whose livelihoods depend upon the visitor industry whereas the Dairy will be employing very few. Please explain how this can be good for our community.

Hawaiians had sustainable ag without milk. Milk is well known to not be good for human consumption. If the milk is shipped off island to be processed how is this sustainable ag and where is the economic validity in such a process? Who is going to make money?

How will the dairy operations impact the local roads? Will more roads need to be built? What are the traffic implications on already congested roads? Will more roads be built in the Valley? If so how will this impact the environment?

What are the implications of the island wide increased bovine populations on our island as a whole?

How can this EIS be non biased with Group 70 as the provider?

This is a Sacred Place please let's treat it with the respect it deserves and do everything that can be done to ensure that there is no damage to this area.

Thank you for your consideration.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Yojana Grace:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The Environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawaii Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawaii at Manoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawaii." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass

growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawaii soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawaii Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kauai and Ni'ihau region of the Hawaiian Islands

has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau,

and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural

botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kauai but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila musaphila*, the only Kauai species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawaii for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kauai and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōloa and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawaii Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plascch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect impacts, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk

Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface

Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed. The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

TRAFFIC: The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site is via Māhā'ulepū Road, a two-way, two-lane road, which is accessible from Kōloa Road (Highway 530) via Ala Kinoiki Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from Māhā'ulepū Road.

Roadways in the project area operate smoothly with no periods of heavy traffic. On average, traffic in the region is much lower than urban areas in the state due to the low population of Kaua'i and rural agricultural demographics of the south Kaua'i

area and Māhā'ulepū. Traffic on Māhā'ulepū Road consists of agricultural vehicles, residential and resort visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhā'ulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoiki Road and Kōloa Road was 8,000 and 6,500 cars daily; HDF-related traffic would add less than one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoiki Road and Kōloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawai'i Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.1.9.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

To Whom It May Concern:

I am writing as a concerned citizen and business owner in Poipu, Kauai that would be greatly affected by the proposed Hawaii Dairy Farm site near the coastline of Maha'ulepu. Should a dairy farm be allowed to put cows near an already contaminated stream it could not only affect the marine life in our small community, but our island's entire economy. Our main source of income for the island is tourism. The proposed dairy site is on one of the most pristine destinations on our island with historical significance and the home to endangered species. I personally live in the area that would be affected by the constant smell of feces and flies as do the majority of my employees. My husband and I also own a vacation rental management company with the majority of our properties in the Poipu area. I can say for certain that NO ONE will want to stay in Poipu if they have to endure that kind of environment. They will go to Maui or perhaps not even come to Hawaii at all. As a licensed real estate broker on Kauai I know that our overall property values will also be greatly diminished.

I strongly urge you to oppose the construction of a commercial dairy farm at Maha'ulepu.

Sincerely,

Amy Grant, R

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4)2-9-003: 001 portion and 006 portion
(4)2-9-001:001 portion

Dear Amy Grant:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Placch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the

development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E

and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane

plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running

maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater

through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or

and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipu region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the

NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of

panels, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE

An Environmental Impact Statement (EIS) is being prepared voluntarily by the Applicant to assess potential environmental impacts and mitigation measures associated with agricultural operations at Hawai'i Dairy Farms (HDF) at Maha'ulepu, Kauai.

To assist in preparing the EIS, an Environmental Impact Statement Preparation Notice (EISPN) was recently published. A 30-day public comment period on the EISPN ends February 23, 2015. The purposes of the publication and comment period are two-fold:

- 1. to allow individuals and groups to request to become a consulted party; and
- 2. to provide written comment regarding effects of the proposed action.

NOTE: Submitted comments will be published in the Draft EIS

Name: SIM HADWIN Organization: SELF

Preferred contact Method

Email: shadwin@csupply.net Postal Address: 2640 PUKOHU RD #114
Phone: (Optional) KOHA

Comments: It is a matter of record that the stream adjacent to the Sim Hadwin property contains a variety of potentially harmful bacteria. I would like to see the State allow HDF to do the necessary (but) situation of being the central level below allowable standards. Does the introduction of additional livestock??

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Jim Hadwin:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series; Surface lavas of the Napali

formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed, rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of

Jim Hadwin
May 26, 2016
Page 2 of 6

groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built

facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to

create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients, Effluent, Irrigation, and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the

Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE GROUP 70 INTL

An Environmental Impact Statement (EIS) is being prepared voluntarily by the Applicant to assess potential environmental impacts and mitigation measures associated with agricultural operations at Hawai'i Dairy Farms (HDF) at Maha'ulepu, Kauai.

To assist in preparing the EIS, an Environmental Impact Statement Preparation Notice (EISPN) was recently published. A 30-day public comment period on the EISPN ends February 23, 2015. The purposes of the publication and comment period are two-fold:

1. to allow individuals and groups to request to become a consulted party; and
2. to provide written comment regarding effects of the proposed action.

NOTE: Submitted comments will be published in the Draft EIS

COMMENT

Name: Kathleen Hadwin Organization: N/A - Resident

Preferred contact Method

Email: mcgram@bigsky.net Postal Address: 2640 Puuholo Rd, #114
Phone: (Optional) 406-499-4184 Kaha, HI 96756

Comments: Please do NOT allow Hawai'i Dairy Farms to use the Maha'ulepu area for their business. There is no way to "grass feed" over 600 cows on 578 acres. There is absolutely no way to guarantee "zero discharge" into the soil, stream and ocean. During floods and heavy rains, the holding ponds will spill over. If a few cattle were grazing on this land the plan would most likely work with the number of cows planned, and most will be present when they arrive there is now way the land and area will not be ruined. PLEASE ALLOW MAHA'ULEPU TO REMAIN THE UPLIVE AND BEAUTIFUL PLACE IT IS TODAY.

Thank you, Kathleen Hadwin

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Maha'ulepu Road
Kauai, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Kathleen Hadwin:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Maha'ulepu Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the sebacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kāua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kāua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kāua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional

capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kāua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCGS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to

encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hāupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling

within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three

times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻiipū region were also calculated. Nitrogen input to the marine environment in the Poʻiipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻiipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at

levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kauai community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Subject: Comments on proposed dairy farm
Date: Monday, February 23, 2015 10:44:06 AM

To Whom it May Concern:

I'm writing to express my opposition to the dairy farm proposed in the Maha'ulepu Valley as it is currently structured. While I appreciate the intention of promoting sustainable food practices for Kauai, I don't feel a dairy of the size proposed is appropriate for this special island. I won't go into all the reasons for opposing this operation...I know you have heard them from people more knowledgeable and eloquent than I...but I *did* want to participate in letting my concerns be known to those in decision-making positions!

Please take great care and consideration in determining if and how this plan should go forward. Kauai is an extremely unique gem on this planet and I do believe it can be a shining example to the world of how sustainability can be done RIGHT (and preferably organically, in my humble opinion). Please don't just green-wash with all the right words; truly examine all the motives behind your decisions and do the right thing.

Mahalo for your time and consideration,
Beth Hagan

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4)2-9-003: 001 portion and 006 portion
(4)2-9-001:001 portion

Dear Beth Hagan:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United

States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be

healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will

benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

Subject: Dairy Farm
Date: Monday, February 23, 2015 11:07:07 AM

To Whom it May Concern,

I'm writing to express my opposition to the proposed dairy farm at Maha'ulepu. It seems to me that if the goal is to do something sustainable, the amount of cattle on the land is truly more of a gamble than sustainable. If you want to do something agricultural (and cattle and agriculture are two different things) with an ecologically minimal impacts, why not do something with native plants and do it organically?

Let's think very, very long term.

Sincerely,
Pat Hagan

Dear Pat Hagan:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Maha'ulepu Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations

(CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the

cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and

other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ūleptū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The

endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kauai; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kauai in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of

Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kauai, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: HDF Industrial Dairy Proposal

Dear Ms. McIntyre:

Attached please find my letter which expresses my concerns regarding the proposed industrial dairy for the South Shore of Kauai as well as my specific comments on the EISPN.

Thank you for your review and consideration of my comments. As you know, the EISPN is a critical component of the overall EIS process and I value this opportunity to provide my input.

Sincerely,

Julie M. Hagensen
Koloa, HI
(808) 742-6688

Dear Ms. McIntyre,
This letter is to express my grave concerns regarding the proposed Industrial Dairy on the South Shore of Kauai. I have owned a home in Poipu with my mother for nearly thirty years and am very familiar with site HDF proposes for their operation. I have read their materials thoroughly and have researched information concerning the many problems associated with such a large scale operation – most notably contamination of drinking water, groundwater, surface water and soils. Although effects on the environment and public health are my primary concern, I am also concerned about the economic and community impacts that the industrial dairy will have on the tourist industry, home values, cultural sites, and local business.

I have concluded that Maha'ulepu is the wrong location for such an operation and urge The Department of Health to do the right thing for the environment, the people and businesses of Kauai.

My comments on the EISPN are centered on the potential cumulative effects of an industrial dairy and the areas I feel must be addressed in the EIS.

Criteria 8: Is individually limited but cumulatively has considerable affect upon the environment or involves a commitment for larger actions.

The HDF plan is not individually limited in its effect on the environment, the economy or the social wellbeing of the community. A responsible EIS will need to address the numerous impacts on water, air and soil quality, threatened species, coral reefs and the local economy. Cumulatively, over a relatively short period of time, the HDF operation will compound the negative effects in all these areas.

The HDF plan does involve a commitment to a larger action. According to EIS requirements, any proposed action must be described in its entirety. HDF plans to begin operations with 699 cows to avoid classification as a CAFO and acknowledges plans to grow the herd to 2000 over time. Therefore the EIS must address the ultimate herd size and its management now. Questions such as composition of cows (eg, the mix of dry and milking cows), how all animals (cows, calves, bulls) will be fed, housed, transported, slaughtered (bull calves and non-producing cows), and the management of their wastes must be addressed at the 2000 cow mark.

In addition to the growth and accumulation of pollutants as the herd size increases, other effects from greater numbers must be estimated and addressed. These include but are not limited to: **noise** from bawling and distress calls from cows separated from their calves which can go on 24-7 for days as well as the loud, anxious calls from cows in heat. How far will these noises carry? Data using climatic, wind and geographic conditions of the specific site must be used; **Odor sources and levels** from each and every aspect of the operation from lagoons and wash areas to liquefied manure that is sprayed on the land. Reports from farmers acknowledge that it takes days for the odors to subside and when it rains it begins again. On even slight slopes not only pollution and contaminants are carried off site but also accompanying foul odors. An analysis up to the 2000 cow mark must

again be specific to the geography, weather and wind conditions at and near the site. How far will these odors travel on a good day? A bad day? Average wind and climatic conditions will not suffice. The **impacts to soils, groundwater, streams and ocean** from dairy wastes including the use of hormones, antibiotics, and vitamins must be again addressed at the 2000 head level.

HDF proposes a zero discharge operation. By its very nature, discharges to lagoons, run off from cleaning and milking operations and direct discharges from cows on sloped lands cannot be viewed as a “zero discharge” and will, together, have a cumulative impact to underground water resources, streams, ditches, beaches, and ocean below. To consider the thousands of sources of pollution from this operation as “nonpoint” is also a misnomer. For each contaminant there is a source. Obtaining a zero discharge NPDES permit is not useful in this case as it will not take into consideration the hundreds, if not thousands, of point sources of pollution that will accumulate at the site, adjacent lands, and downslope beaches, caves and ocean. As clearly demonstrated by both US EPA and citizens in the State of Washington, drinking water wells as little within a few mile from a feedlot or dairy have been contaminated over time. In the state of California, land has been declared hazardous and unusable due to years of dairy farm operation.

As noted in the DOH and SurfRider water quality samples, pollution levels in the Waipili stream already far exceed State and Federal water quality standards. The addition of 699-2000 cows and a large scale milking operation will only compound a situation that is already detrimental to human health and the environment.

The HDF EIS must address the following cumulative effects from its operation:

1: **Former uses and treatment of the land.** Describe any and all former uses of the site, including adjacent lands. Provide data on current conditions of soils, flora, fauna, air and water. This is necessary to set a baseline and to monitor future cumulative effects resulting from the proposed HDF operation. Note: This must include any and all alterations to the landscape started or completed by HDF prior

to the EIS, including the permits obtained or required. It must also include the mitigation efforts HDF will take to contain, decrease, and repair accumulated pollution levels already in existence on site. Also detail how will this work will be monitored and by whom.

2. **Present uses of the HDF site and adjacent lands** --agricultural, industrial and human related-- including the taro farm located at the bottom of the HDF site and the quarry located NW of the cave. This must include Human recreational uses such as pig hunting, hiking, and bathing. For example, HDF must explicitly outline provisions it will take to protect the taro farm from any incursions or adverse effects to the soils and food value of the crop.

3. **Future uses of the HDF site and adjacent land** should the dairy fail. Address the potential adverse effects from soil and groundwater contamination on the land that will or may limit future uses.

4. **Cumulative Weather conditions** and effects on the proposed operation. Historical data of rain fall, flooding, high winds and hurricanes must be examined in the context of reliable probabilities of flooding, runoff, destruction of buildings, paddocks and lagoons resulting in contamination of beaches below and South shores. Worst case scenarios must be described as well as impacts to human health and the environment.

5. **Cumulative Economic effects:** The EIS must address cumulative effects, over time, on property values, the tourist/hospitality industry and small businesses in the area. As noted in other locations where large dairies have operated, there will be a cumulative effect on public knowledge of odors, flies, and pollution. Perhaps initially the effect will be small but word of mouth, articles in magazines and trade journals will impact a vibrant industry that currently accounts for a large percentage of the island's financial resources. The ripple effect could eventually affect the entire island in terms of jobs, property values and taxes , and indeed all businesses who depend on tourists for their livelihood.

Thank you for your review and consideration of my concerns.

ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE

An Environmental Impact Statement (EIS) is being prepared voluntarily by the Applicant to assess potential environmental impacts and mitigation measures associated with agricultural operations at Hawai'i Dairy Farms (HDF) at Maha'ulepu, Kauai.

To assist in preparing the EIS, an Environmental Impact Statement Preparation Notice (EISP/N) was recently published. A 30-day public comment period on the EISP/N ends February 23, 2015. The purposes of the publication and comment period are two-fold:

1. to allow individuals and groups to request to become a consulted party; and
2. to provide written comment regarding effects of the proposed action.

NOTE: Submitted comments will be published in the Draft EIS

Name: Julie Hagensen Organization: _____

Preferred contact Method

Email: julie.hagensen@comcast.net Postal Address: 2311-B Kane Rd. Koloa HI 96756

Phone: (Optional) _____

Comments: As a former regulator with over 10 years experience regulating dairies in the State of Washington, I would raise concerns regarding the safety of an Individual Dairy in Mahe'ulepu.

During the EIS Phase HDF must analyze all possible sources of pollution and their potential effects on human health and the environment. This must be done at the 2000 head target and include cumulative impacts over time. Based on my experience and every thing I have read concerning HDF's plan, I must conclude that this is the wrong location for an Individual Dairy. Good science told County some must prevail.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Maha'ulepu Road
Kauai, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Julie M. Hagensen:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

Your comments were received by the State of Hawai'i Department of Health Environmental Planning Office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699, mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Maha'ulepu Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of

the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups

known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during drier periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The

report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luualalei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon

dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS) including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhāʻulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kāua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kāua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhāʻulepū region during and following the hurricanes that affected Kāua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhāʻulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kāua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhāʻulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

NOISE: Existing noise conditions of the project site and the surrounding Māhā'ulepū valley area are evaluated in the Draft Environmental Impact Statement (EIS), along with anticipated short-term and long-term noise conditions associated with the dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai'i Department of Health (DOH) rules use the A-weighting sound network (dBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes. The Hawai'i Dairy Farms (HDF) site in Māhā'ulepū Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition, occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 78 decibels or that cost a total of more than \$250,000. Mitigation measures to minimize construction noise will include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk

Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface

Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the Indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of

air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were

Julie M. Hagensen
May 26, 2016
Page 16 of 16

applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Vivian Hager:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations

(CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the

cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and

other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day.

Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development.

The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the

current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāūlepu will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality

monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dired manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient

air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM_{10} is 2.01 $\mu\text{g}/\text{m}^3$, well below the State standard of 150 $\mu\text{g}/\text{m}^3$. The estimated concentration for $PM_{2.5}$ is 0.23 $\mu\text{g}/\text{m}^3$, well below the Federal standard of 35 $\mu\text{g}/\text{m}^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

To Whom It May Concern:

As a long time resident of the Poipu area in South Kauai, I would like to express my vehement opposition to the proposed Maha'ulepu dairy farm, which is in the planning stages in South Kauai. My family has reviewed all of the pertinent facts surrounding this project, which has not been well planned from the outset.

The very thought of invading a pristine residential environment, coupled with a premier resort complex, is ill advised at best. The many faceted negative ramifications of this proposed project are obvious to the most uninformed group of residents on Kauai.

At the top of the list is the destruction of the current traditional environment, nurtured by the Hawaiian community.

The negative impact on the water supply is certainly paramount in the lengthening list of problems that the local community is facing. This is closely followed by the odor, which will grossly affect the standard of living in nearby communities. These key factors are followed by the fly infestation, which will be evident and indefensible.

The health problems will be inflated immeasurably and should fall under the jurisdiction of the environmental authorities.

Initial tests on the water supply in the area are irrefutable, inasmuch as they prove beyond a reasonable doubt that the water supply in the future will be affected by the increasingly large herd of cattle.

With regard to the tax base on the Island of Kauai, it is predictable that real estate prices will decline, hence, lowering the real estate taxes collected by the County of Kauai should the project move forward. Your appropriate negative action relating to his matter, will be most appreciated, not only by my family, but to the large group of voters on the island of Kauai.

In the interests of all concerned, if the project was moved to a more suitable location, it would resolve this issue immediately.

Respectfully submitted,

John & Terri Halliday

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Maha'ulepu Road
Kauai'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear John & Terri Halliday:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau,

and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in BIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests

are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila melanogaster*, the only Kaua'i species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōba-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōba and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plascch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction

employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E

and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane

plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kālāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running

through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or

maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater

and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970 (CAA)*, amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards (SAAQS)* that are as strict or, in some cases more strict than the

NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of

panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezonning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The

alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Comments to be considered in preparation of an Environmental Impact statement for:

Project Name: Hawaii Dairy Farms

Island: Kauai

District: Poipu

TMK: (4) 2-9-003:001 (portion); 006 (portion)

(4) 2-9-001:001 (portion)

To whom it may concern:

Waters of the State and United States:

The scope of the EIS must include a thorough consideration of the Public Trust Doctrine as articulated by Article XI of the Constitution of the State of Hawaii. The Hawaii State Supreme Court has authored at least four major Decisions enforcing the Public Trust Doctrine and its constitutionally intended protection for the waters of the State: *Waiahole I* (1994), *Waiahole II* (2000), *Na Wai 'Eha* (2012), and *Kauai Springs* (2014). Each of these cases dealt with situations in which water on agricultural land was either being diverted or taken for use by an agricultural operation or bottling company. In all cases the Court found that such uses constituted a violation of the Public Trust Doctrine. There is no reference to this doctrine in HDF's EIS. Hawaii Dairy Farm's Waste Management Plan also fails to refer to or consider this doctrine. It needs to be addressed by both HDF's Plan and the EIS.

Hawaii Dairy Farms (HDF) plans to irrigate the pastures at the Maha'ulepu site with 2.93 million gallons of water daily (MGD) from the Waita Reservoir according to HDF Waste Management Plan (WMP), pages 31, 37 and 44. Per HDF, their lease with Grove Farm entitles them to 3 MGD (million gallons daily) as a term of their lease contract. It may not be uncommon to have an agricultural lease include use of water that is available on the agricultural site. In this case, however, the water that is available from the Waita Reservoir, an off-site reservoir that happens to be on other Grove Farm property, is water that collects from the Huleia Stream diversion which now feeds the Waita since the cessation of cane cultivation in 1996. The volume of water HDF plans to consume with irrigation of its 517 acres of grazing pasture (2.93 MGD) is substantial. But for the 100% diversion of the Huleia Stream, the Puna District

used to receive water from the Huleia Stream, previously a major water resource for the natural watershed of the Niamalu River, the Alekoko Fishponds and several native Hawaiian taro farms. The farmers of the Puna District (covering the area where the Huleia waters flowed prior to the construction of the 100% diverter in 1957) are currently involved with the Department of Land and Natural Resources (DLNR), Commission on Water Resource Management (CWRM) seeking restoration of the natural watershed and revision/take down of the Huleia Stream diversion. HDF's planned water consumption from the Waita (2.93 MGD) far exceeds the Kaua'i Springs 1000 (5 Gallon) containers of water per day that Kaua'i Springs planned to draw from the stream flow. Kaua'i Springs, Hawaii Supreme Court, SCWC-29440, 28-FEB-2014, pages 3-4. If the Public Trust Doctrine applied in Kaua'i Springs it should certainly be a compelling consideration with the planned use of 2.93 MGD. Not only is the intended daily volume of water an issue, but of equal concern is the proposed new use of the water, the liquification of massive amounts of waste (3 million gallons of wet manure and 200,000 gallons of urine monthly from the start-up herd of 699 and 8.5 million gallons of wet manure and at least 600,000 gallons of urine monthly if the herd reaches 2,000 as planned). Clearly, a thorough evaluation of HDF's proposed new use for the waters of the Waita is warranted as well as a detailed analysis of the impact to "instream" and "out of stream" or "nonstream" flow standards.

Grove Farm acquired the Koloa Sugar Plantation which, like most sugar plantations, relied on an extensive ditch system to irrigate its crop. The Huleia Stream diversion, (a lengthy concrete diverter, covered by a steel grate that was designed to divert 100% of the instream flow of the Huleia Stream, located maika of the Kaunua'i Highway/Route 50) provided the great majority of the waters relied on by Grove Farm for cultivation of the Koloa Sugar Company's cane. When Koloa Sugar ceased operation in 1996, the extensive irrigation system was no longer in use. The 100% diversion of the Huleia Stream was never revised despite the substantial decrease in need once the Koloa Sugar Company ceased its operations. Thereafter the diverted waters continued flowing from the Huleia and flowed to the Waita Reservoir. The Waita has since become the largest reservoir in the State of Hawaii. There is little question that these waters are waters of the State coming from the South slope of the Kilohana crater in Kahili Mountain. The water runs from the 100% stream diversion into a concrete catchment and then flows through a tunnel in the Hauapu Mountain range, ending in the Waita Reservoir. The EIS needs to include HDF's proposed new use and its probable impacts as well as an analysis and evaluation of the degree of impact from the proposed use on the existing downstream users, instream flow, instream habitats, and dependent wildlife species. Although generally accepted that water use is included in the leases for agricultural parcels, the daily quantity of water needed for the proposed HDF operation (2.93 million gallons per day from the Waita) plus the potable water to be drawn daily from the Maha'ulepu wells far exceeds the typical agricultural use on Kaua'i.

In *Re 'Iao Ground Water Management Area High-Level Source Water Use Permit Applications and Petition to Amend Interim Instream Flow Standards of Waiahe'e River and Waiau, 'Iao, Waikapu Streams Contested Case Hearing* Hawaii Supreme Court, No. SCAP-30603 August 15, 2012, the Court concluded that the Water Commission (WRM) erred in balancing instream and noninstream uses, and therefore, the Interim Instream Flow Standards (IIFS) do not properly protect traditional and customary native Hawaiian rights, appurtenant water rights or the public trust. p. 3. Based on the cultural practices as well as the historic and archeologic sites of Maha'ulepu, there is an equal if not greater risk at Maha'ulepu. The EIS needs to consider, environmental concerns, native Hawaiian practices, outdoor and recreational activities, and aesthetic and scenic values, as required by the water code. p. 12-13 Those considerations are equally important the analysis of "offstream public trust uses, such as the public water supply." p. 16. "...the water code and our case law interpreting the code have affirmed the Commission's duty to establish IIFS that 'protect instream values to the extent practicable' and 'protect the public interest'." In *re Water Use Permit Applications "Waiahole II", 105 Hawaii 1, 11,*

93 P.3d 643, 653 (2004); HRS § 174C-71(2)(A). Clearly this must be addressed and study in full by the EIS.

In Kauai Springs the Court concluded that the water Kauai Springs uses for its operations originates from an underground spring located several miles from the Property, 1,000 feet up Kahili Mountain.¹ Kauai Springs apparently “purchases” or “licenses” its water from EAK Knudsen Trust (Knudsen Trust), the owner of the land where the spring is located. The water is transmitted to the Property by a private, gravity-fed system dating back to the 1890s, which is owned by Knudsen Trust and operated by Grove Farm Company (Grove Farm).² Hawaii Supreme Court, SCWC-29440, 28-FEB-2014, pages 3-4.

^{fn1.} Contrary to the findings of the circuit court, the EAK Knudsen Trust does not “own the spring [or] the water.” See, e.g., In re Water Use Permit Applications, 94 Hawaii 97, 129, 9 P.3d 409, 441 (2000) (“a public trust was imposed upon all the waters of the kingdom. That is . . . not ownership in the corporate sense . . . rather . . . a retention of such authority to assure the continued existence and beneficial application of the resource for the common good.”)

^{fn2.} According to the State Public Utilities Commission (PUC), “[t]he Grove Farm water system originates at one of two tunnels located on the land owned by the [Knudsen Trust] at the foot of Mount Kahili The water line delivers water to Kahili Mountain Park and a number of domestic and agricultural users on various Knudsen Trust-owned and other parcels on its way to Koloa Town, where it supplies at least eleven residential lots on Waihoan Road.”

In Kauai Springs, the State Department of Health offered “[t]here may be the potential for ground or surface water degradation/contamination,” and therefore “recommend[ed] that approvals for this project be conditioned upon a review by the State Department of Health and the developer’s acceptance of any resulting requirements related to water quality.”⁶ The Water Commission further commented that “[g]round-water withdrawals from this project may affect streamflows, which may require an instream flow standard amendment.” Finally, the Water Commission stated that although a water use permit was not required because the island of Kauai was not a designated ground-water management area, other permits from the Water Commission may be required if the source of Kauai Springs’ water was modified:

The Island of Kauai has not been designated as a ground-water management area; therefore a water use permit from the Commission is not required to use the existing source(s) or to change the type of water use. However, if the source needs to be modified in any way, a well modification permit from the Commission may be required. In addition, if a pump is to be installed to induce additional water flow, a pump installation permit from the Commission would be required. If the source is modified to induce additional water flow, and the modification results in impacts to surface waters, a petition to amend the interim instream flow standard for affected surface waters must be made and approved prior to use of the water.

Kauai Springs, Supreme Court, SCWC-29440, 28-FEB-2014, page 10.

^{fn6.} The State Department of Health (DOH) offered several “environmental health concerns” for the Planning Commission to consider, regarding: 1) sanitary facilities and disposal of wastewater; 2) the water bottling facility’s compliance with applicable ventilating requirements; and 3) air pollution control measures. The DOH concluded that “[d]ue to the general nature of the application submitted,” it “reserve[d] the right to implement future environmental health restrictions when more detailed information is provided.”

^{fn8.} A “public utility” is defined as “every person who may own, control, operate, or manage as owner, lessee, trustee, receiver, or otherwise, whether under a franchise, charter, license, articles of association, or otherwise, any plant or equipment, of any part thereof, directly or indirectly for public use . . . for the production, conveyance, transmission, delivery, or furnishing of . . . water[.]” HRS § 269-1 (Supp. 2012). Supreme Court, SCWC-29440, 28-FEB-2014, page 14

“because it involves the use of an important public trust resource - fresh water - for personal financial gain,” Supreme Court, SCWC-29440, 28-FEB-2014, page 17. This is all relevant to the HDF proposed industrial dairy as HDF’s impact is certain to be of much greater consequence to the Hulei Stream flow standards than Kauai Springs ever intended to be.

In fact, in Kauai Springs, the Office of Hawaiian Affairs (OHA) argued that the Commission “uphold its public trust responsibilities by denying Kauai Springs’ permit applications without prejudice, until the applicant can show, and the appropriate agencies can concur, that Kauai Springs’ proposed use is reasonable-beneficial and will not interfere with public trust purposes.” Supreme Court, SCWC-29440, 28-FEB-2014, page 18. Shouldn’t Maha’ulepu deserve the same if not greater protection for its rich sites, cave reserve, habitats, delicate ecosystem when a much greater environmental impact is threatened by the proposed industrial dairy than that posed by Kauai Springs.

^{fn9.} For example, the public trust doctrine requires an applicant to demonstrate the feasibility of alternative sources of water. The findings do not indicate whether Applicant complied with this requirement. “[P]ermit applicants must . . . demonstrate the absence . . . of alternative water sources. Such a requirement is intrinsic to the public trust[.]” Waihoale I, 94 Hawaii¹ at 161, 9 P.3d at 473; see also Kukui (Molokai), Inc., 116 Hawaii¹ at 496, 174 P.3d at 335 (“The [agency] cannot fairly balance competing interests in a scarce public trust resource if it renders its decision prior to evaluating the availability of alternative sources of water.”)

Supreme Court, SCWC-29440, 28-FEB-2014, page 105

The Court held: “f. To assist agencies in the application of the public trust doctrine, we distill from our prior cases the following principles: ²⁵

- a. The agency’s duty and authority is to maintain the purity and flow of our waters for future generations and to assure that the waters of our land are put to reasonable and beneficial use.²⁶
- b. The agency must determine whether the proposed use is consistent with the trust purposes:

^{fn25.} We provide this framework for assistance and do not indicate that it is mandatory or that it precludes other analytical approaches that are consistent with the public trust doctrine.

^{fn26.} Waihoale I, 94 Hawaii¹ at 138, 9 P.3d at 450.

- i. the maintenance of waters in their natural state;
- ii. the protection of domestic water use;
- iii. the protection of water in the exercise of Native Hawaiian and traditional and customary rights; and
- iv. the reservation of water enumerated by the State Water Code.

c. The agency is to apply a presumption in favor of public use, access, enjoyment, and resource protection.²⁷

d. The agency should evaluate each proposal for use on a case-by-case basis, recognizing that there can be no vested rights in the use of public water.²⁸

e. If the requested use is private or commercial, the agency should apply a high level of scrutiny.²⁹

f. The agency should evaluate the proposed use under a “reasonable and beneficial use” standard, which requires examination of the proposed use in relation to other public and private uses.³⁰

Applicants have the burden to justify the proposed water use in light of the trust purposes.³¹

^{fn27.} Id. at 142, 154 n.59, 9 P.3d at 454, 466 n.59

^{fn28.} Id. at 141, 9 P.3d at 453; Kukui (Molokai), Inc., 116 Hawaii¹ at 490, 174 P.3d at 329.

^{fn29.}29 Wai-hoale I, 94 Hawaii¹ at 142, 9 P.3d at 454.

^{fn30.} Id. at 161, 9 P.3d at 473.

^{fn31.} Kukui (Molokai), Inc., 116 Hawaii¹ at 490, 174 P.3d at 329.

a. Permit applicants must demonstrate their actual needs and the propriety of draining water from public streams to satisfy those needs.³²

b. The applicant must demonstrate the absence of a practicable alternative water source.³³

c. If there is a reasonable allegation of harm to public trust purposes, then the applicant must demonstrate that there is no harm in fact or that the requested use is nevertheless reasonable and beneficial.³⁴

d. If the impact is found to be reasonable and beneficial, the applicant must implement reasonable measures to mitigate the cumulative impact of existing and proposed diversions on trust purposes, if the proposed use is to be approved.³⁵

^{632.} Wai-hole I, 94 Hawai'i at 162, 9 P.3d at 474.

^{633.} Id. at 161, 9 P.3d at 473.

^{634.} Kukui (Molokai), Inc., 116 Hawai'i at 499, 174 P.3d at 338.

^{635.} Wai-hole I, at 143, 161, 9 P.3d at 455, 473.

^{636.} The ICA held that the circuit court's COI's § 63 (record was "devoid of any evidence that Kauai Springs['] existing or proposed uses might affect water resources subject to the public trust"), § 71 and § 72 (suggesting that Planning Commission "may" have public trust duties in this case) were "incorrect in that they do not recognize the Planning Commission's public trust duty to consider and review Kauai Springs' water usage in its water bottling operation." Kauai Springs, 130 Hawai'i at 423, 312 P.3d at 299. In its Application, Kauai Springs does not challenge the ICA's conclusion that the Planning Commission had a duty to consider Kauai Springs' water usage in reviewing its permit application. Rather, Kauai Springs argues that the ICA erred in vacating the circuit court's COI's because the circuit court recognized the Planning Commission's public trust duties and correctly found that the Planning Commission fulfilled these duties.

Supreme Court, SCWC-29440, 28-FEB-2014, pages 85-88

Alternatives:

In the EISPN, the discussion of alternatives, offering only one other location to be considered, fails to satisfy a real alternative evaluation for an operation that is well known for its significant adverse environmental impacts. Clearly, the EIS should explore at least three other locations at a minimum.

In its discussion of a Confined Dairy Operation Alternative, HDF proposes a "Confined Dairy Operation". Assuming the public trust water rights are adequately protected and preserved, if HDF chooses to proceed with a true CAFO, the EISPN offers only that "the Maha'ulepu location would require additional manure management as nutrients would not be returned to pastures. Additional grain and forages would be imported to sustain dairy cows. The Confined Dairy Operation Alternative would utilize large barns to house and feed the cows. Animals would be confined within the barns and milking parlor; no pasture area would be required. No manure would be deposited on pasture grasses and grass would not be utilized as a locally available feed source." The EIS must address why feed cannot be cultivated on the property, why a methane digester cannot be implemented saving electricity consumption from the Grid that would also help to collect manure, lowering the odor, fly and other pest problems to potentially feasible levels. To address alternatives, the scope of the EIS must be expanded to include these and other related considerations.

Important Agricultural Land (IAL), Hawaii State Constitution, Article XI, Section 3.

The EIS must consider HDF's website boast that it intends to be "the first commercial use of IAL land". Is that what the State intended when the provisions of the IAL enactments were adopted? Is IAL land even appropriate for a commercial agricultural operation? This must be addressed by the.

HDF's claim that their proposed industrial dairy will lead to agricultural self-sufficiency must be substantiated in the EIS, especially when the WMP calls for shipping the milk off island, selling the milk wholesale to another company who would then process, bottle and distribute for sale at locations they select.

Sugar cane cultivation has left the proposed farm soils "depleted of essential nutrients" pg 56 HDF WMP, Section 8.1. The EIS needs to substantiate the scientific support for their claim that the proposed dairy would in any way improve the soil at Maha'ulepu. Hooves from 1200 pound cows are in themselves degrading to soil, contributing to erosion and nutrient loss. The addition of nutrients does not remediate soil and the EIS needs to address the claimed benefit of an industrial dairy to the soil composition at Maha'ulepu.

Table 5 - Potential Impact Categories for Liner Failure

1. Any underlying aquifer is at a shallow depth and not confined
2. The vadose zone is rock
3. The aquifer is a domestic water supply or ecologically vital water supply
4. The site is located in an area of solubilized bedrock such as limestone or gypsum.

Considerations for Minimizing the Potential of Waste Storage Pond Liner Failure.

Sites with categories listed in Table 5 should be avoided unless no reasonable alternative. 313 p 6 of 7
NRCS, PI
April 2012

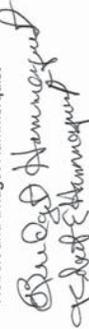

Table 4 - Potential Impact Categories from Breach of Embankment or Accidental Release

1. Surface water bodies -- perennial streams, lakes, wetlands, and estuaries
2. Critical habitat for threatened and endangered species.
3. Riparian areas
4. Farmstead, or other areas of habitation
5. Off-farm property
6. Historical and/or archaeological sites or structures that meet the eligibility criteria for listing in the National Register of Historical Places.

Cultural Practices, Historical and Archeological Sites are all at risk. The foregoing considerations are from the NRCS manual stapled to the back of the WMP but were not specifically incorporated in or addressed by the WMP. The EIS needs to address these aspects of the NRCS and others as well to cover this risk which from our present evaluation, especially based on the findings of the Custom Soil Resource Report of the NRCS, dated June 5, 2014.

Respectfully,

Robert and Bridget Hammerquist

Subject: Hawai'i Dairy Farms
 Environmental Impact Statement Preparation Notice
 Māhā'ulepū Road
 Kaua'i, Hawai'i

TMK: (4)2-9-003: 001 portion and 006 portion
 (4)2-9-001:001 portion

Dear Bridget Hammerquist:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations

(CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any pose; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the

cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and

other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Ka'ena Clay Brown Variant at 29 percent, and Luulualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking

parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface

Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the Indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits,

costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Comments submitted regarding HDF Environmental Impact Study (E.I.S.):

Aloha,
My legal and hereditary name is *Kalimikūmā Ka Mōka'uli'uli 'O Na Ali'i Hanohano*. I was born in, and am a native resident of Koloa, Kaua'i. I am established (SHPD), as a lineal descendent of the original Stewards (7th generation), of the Koloa Moku, or District, which includes *Maha'ulepu*. My *Kupuna's* - "Anakala" or Uncle, *Kalūhimoku Nakapa'ahu*, was a noted native medicinal practitioner (Marvin Brennecke 1953), who gathered medicinals in *Maha'ulepu* and *Pa'a*. His father, *Kalipoloahilani Nakapa'ahu*, *Ali'i Nui* of Koloa District (*Moku*), owned, and resided on a nine acre parcel in *Aweoweoani* (Hidden Valley, adjacent to *Maha'ulepu*). I have followed in his footsteps for more than a quarter century. As a native spiritual practitioner representing a registered Hawai'i non-profit interfaith Ministry (*Hui Hanā*), continuing cultural practices and observances at *Maha'ulepu*, this Dairy will affect cultural resources that I am dependent upon. I proclaim myself to be a vested party-at-interest seeking intercession status.

As a participating member of the *Ilioula 'okalani* Coalition, alert to incursions or intrusion on Cultural sites or practices; as Pastor of "*Hui Hanai I ka Honua La'a*" a registered non-profit interfaith Ministry; as Steward of: "*Malama Maha'ulepu*" 501 c-3; "Friends of *Maha'ulepu*" and *Koloa 'Aha Moku* Council, I do not speak for or represent those organizations, but share with them and desire address of their, and my, concerns.

I will be directly impacted by the Dairy installation introducing high volumes of nitrate rich untreated solid waste and urine affecting three precious qualities to which I, and the Community have inalienable rights, that of **Clean Water, Environmental contaminate protection, and Quality of Life**.

Neighbors in the nearby communities of Kaua'i's South-Shore will also be impacted by the degradation of water quality (ocean & aquifers), contamination of soil, odors carried by prevailing winds, or lack thereof, biting flies, affecting residential and Visitor Destination "Quality of Life" issues along with economic collapse of one quarter of the Island's tax-base.

Land and aquatic life in the downslope and drainage watershed from the proposed site will be impacted by the inability of HDF to achieve complete containment of seepage resulting from the Dairy operation into the surrounding areas. This is substantiated by the NRCs Custom Soil findings commissioned, distributed, but not taken into consideration by HDF.

ISSUE of conflict w/ use of Group 70 conducting the E.I.S.: "Group 70" developed the existing Waste Management Plan and prepared architectural blueprints for all of HDF's proposed Dairy installation. As analysis of this Plan and projections has been reviewed by qualified independent experts to contain serious flaws and misrepresentations questioning the credibility of their research and facts, does it not stand to reason that in the interest of propriety and competency, that an unbiased third party conduct the E.I.S.?

HDF & "Group 70" have failed to address: The NRCs Custom Soil Study findings (6/05/14) determining that 50% of the proposed farm soil is at HIGH or VERY HIGH risk of run-off; Issues presented in the Mark Madison review and report (submitted by Kawaioloa Corp).

Point by Point Specific issues needing to be addressed by the E.I.S.:

- 1: (Involving an irrevocable commitment to loss or destruction of any natural or cultural resource): Introduction of Waste material and nitrate inundation will destroy viability of Valley floor's grey hydromorphic soil to birth and produce *Kalo*.
- 2: (Curtailing the range of beneficial uses of the environment; (for plants, animals or humans): Seepage from Dairy operation will irreparably damage viability of the (formerly established) Salt Pans, a sustainable native resource gathering practice unique to Hawai'i among Pacific Islanders.
- 3: No comment at this time.
- 4: (Substantial affectation of the economic or social welfare of the community or State): Pernicious odors, biting flies, noise pollution during seasonal events of wind cessation (*Kona* connective layer zone), beach & shoreline closures due to water bacterial counts plummeting property values, loss of Visitor business, Quality of life impacts with odors, Convention and accommodation cancellations, employment losses, Changes detrimental to the public good.
- 5: (Issues that substantially affect public health): Biting flies, Odors, Water (drinking & Ocean), contamination issues.
- 6: No comment at this time.
- 7: (Involving a substantial degradation of environmental quality): Impact of biting flies, odors, and bacteria from aerosolized and deposited manure, ammonium interaction, nitrate concentration buildup and seepage into proximate ditches and downslope watershed impacting Wetlands, *Kalo* cultivation, aquatic resources, reef, beaches, habilitation, Wilderness quality, as well as native, resident, and visitor recreational experiences.
- 8: (Is individually limited but cumulatively has considerable effect upon the environment or involves a commitment for larger action): The submitted Plan professes to initiate operations with an initial herd size of 699 (gestating) cows, expanding to a milk-producing herd size of 2,000. The Plan fails to address the impact and implications of the increased bovine population distribution island-wide necessary to support the Milking herd.
A reasonable extrapolation of the 1398 (adjustable for attrition), initial added population subsequent to birthing would result in approximately 50% heifers, the remainder would be channelled to Kaua'i's beef industry. Non-gestating, nascent, or pre-gravid cows would add to the supportive and alternative use population. With such increased impact from up to twice the projected herd size being distributed on Island, what plans are in place to process and distribute the increased volume, and what systems are developed to ensure and protect Public and environmental health as a result of the increased presence.
- 9: (Substantially affects a rare, threatened, or endangered species, or its habitat): The protected Hawaiian Blind Wolf Spider and its amphipod prey co-exist in the substrate level of

lava tubes permeating the impacted area; *Nene*, *Limu*, *Opihi*, *Wana*, *He'e*, *Loli*; *Honu*, & Monk Seals, vegetation and sea-life important to Hawaiian culture and PASH resource management populations are at risk from run-off and inundation.

10: **Detrimentially affects air or water quality or ambient noise levels:** Odors, biting flies, bacterial colonies, ambient noise during seasonal cessation of winds, penetration into public water supply, ammonium interactions with the ambient atmosphere affecting vegetative growth.

Issues of Water quality, contamination of public drinking water, penetration of contaminants into the aquifer; soil and lava tube run-off projections calculated to include events such as the 1948 Forty-two day and 2006 30-plus day rain events.

11: (Affects or is likely to suffer damage by being located in an environmentally sensitive area such as a flood plain, tsunami zone, beach, erosion-prone area, geologically hazardous land, estuary, fresh water or coastal water):

Soil categorization by NRCS as High to Very High risk of run-off impacting Wetlands, beach zones, estuaries, tide-pools, reef, coastal and shoreline waters insure eventual widespread damage as suffered by New Zealand, Washington State, Wisconsin and New Mexico.

12: No comment at this time.

13: No comment at this time.

The 2001 Office of Hawaiian Affairs Report to Jennifer Dines of the Federal Communications Commission (FCC) identifies the Haupū Range (including it's *Maha'ulepu* Valley), as a Hawaiian Spiritual Sanctuary and Mausoleum of Ancestral remains. Widespread native burials throughout the region including the single largest Burial Dune in the Pacific (*Aweoweonui*) establish qualification of "Sacred Spaces" designation as defined and protected under the 1978 Religious Freedom Act (American Indian [i.e., *Indigenous natives/ Alaska; Hawaii/ American Samoa*]).

Unmarked sites, burial grounds, ceremonial "*Wahi Pana*", Sub-surface cultural layer material, proximate wetlands known but undisturbed, require a thorough cultural resources study and ensure mitigation measures to ensure protections.

Consider impact to and degradation of indigenous cultural use of natural land and aquatic resources protected under PASH.

Alternative uses of area: Restoration and encouragement of *Kalo* (Taro), cultivation and production of a natural resource (*Kalo*) qualifying for protection under the U.S. Supreme Court [1934] "Religious Freedom" determination that "Catlinite" (Pipestone), was a protected "Spiritual" natural element integral to established indigenous religious practices. The Court codified protections ensuring that the metamorphosed natural ceramic conductive substance, religiously employed as a Spiritual conductor, would be protected and available to recognized tribal members at no cost using traditional seasonal harvesting techniques. (decision subsequently bolstered by President Clinton's 1978 Executive Order).

As it is well established that every part of the process in Hawaiian *Kalo* cultivation, preparation and ingestion is a religious act, in honouring "*Haloa*", a recognized cultural deity, the rare hydromorphic "plastic-like" clay soil providing the optimum conditions for *Kalo* cultivation qualifies for protections under "best and highest use" of the land as well as PASH protection as a rare natural resource culturally sustained in Religious practice.

(similarly protected culturally used natural resources used in Religious practices include *Awa* (*Kava*), *alae* (mineral), "*Ichneich*" (Indian Celery), and *Peyote*).

Alternative agricultural uses: Bio-mass generation. Sustainable energy production; endemic biodiversity and cultivation of medicinal herbs such as *Cats-claw*, *Olena* (Turmeric), crops of Taro, sweet potato or yams, conforming to the "highest and best" sustainable practices of land use.

Falls to address: Overflow discharge of effluent ponds resulting from tropical storm and hurricane rainfall amounts historically recurring with frequency over affected area with high to very high run-off potential.

Proximity of Ditch to Milking facility yard and "lot" sized rotating pens vulnerable to nitrate penetration. "Lots" of open rotating four to five acre fenced parcels, cannot sustain intended herd population size with adequate room, native and introduced grasses, subsequently requiring an estimated 28% supplemental imported grain based feed with no details as to it's source or GMO status. As such, it fits the definition of a "Feed Lot" (albeit rotating) operation subject to additional limitations, controls and restrictions on operation.

Employment of mechanized distribution of aerosolized manure with re-deployable equipment crossing or in proximity to ditches, well sites, or seasonal wetlands used by native endangered waterfowl is in conflict with reviews of current industry standards and practices.

Note: The American Public Health Ass. (also Canada & Michigan) have called for a Nationwide Moratorium on industrialized Dairy operations (2003) such as this present Plan. Does HDF contest or refute these findings? How do they substantiate this?

Implications of the totality of increased cattle populations on Kaua'i resulting from maintaining consistency of Dairy herd size, i.e., How many heifers, steers, cows (inactive or nascent), will be in addition to an eventual Milking herd of two thousand cows?

Issue of a flawed and inadequate Cemetery Plan failing to contain nitrate penetration into downslope watershed. Current projections fail to address aftermath of catastrophic events from weather or disease. Designation of a 694 foot double row of interments two feet apart cannot adequately provide sanitary containment. Furthermore, seepage and penetration into downslope watershed is inevitable and deleterious to the environment.

The watershed of Maha'ulepu Valley (and HDF's proposed 578 acre industrial dairy site) comprises waters from the Haupū mountain range, the *Waiopili* Stream, as well as the irrigation ditches, all of which are "hydro-logically linked" as they emerge and converge at the *Makauwahi* Cave on their direct path to the ocean. Based on that critical feature, all waters being hydro-logically linked, how can HDF protect the wetlands, the endangered species, the reefs, the rare and sacred sites and the ongoing native Hawaiian cultural practices from contamination caused by the massive amounts of wet manure and urine produced daily even with their start-up herd of 699 pregnant dairy cows? Short of lining the entire surface of the proposed farm site, the established hydrological link between the various components of the Maha'ulepu watershed make runoff, discharge and contamination unavoidable.

For the aforementioned concerns and issues raised, I urge that HDF agree to an alternative contractor to perform the E.I.S. and address of all issues raised or alluded to in these comments.

I again urge Olapua, HDF, and Grove Farm Co. to reconsider and relocate their intended Dairy operation to a more appropriate location.

Kalamikumai Ka Maka 'uli 'uli 'O Na Ali'i Hanohano

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Kalamikumai Ka Maka 'uli 'uli 'O Na Ali'i Hanohano:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVE: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The Environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawaii Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāulepū Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhāulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawaii is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and

irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kālihi Clay at 32 percent, Ka'ena Clay Brown Variant at 29 percent, and Luahalei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeological and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The

endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

INVERTEBRATE SPECIES: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators on site that control those species. Fieldwork was conducted during September 15-16, 2014. The entire study is included in Draft Environmental Impact Statement (EIS) as Appendix B.

CAVE AND LAVA TUBE INVERTEBRATES

There are no known caves or lava tubes found at or adjacent to the dairy farm property. The Kōloa Lava Tube System, which provides habitat for two endemic cave species, the Kaua'i Cave Wolf Spider and the Kaua'i Cave amphipod, is located several miles away from the dairy farm property. Both invertebrates are listed as endangered under the U.S. Endangered Species Act. Not all caves in the Kōloa area contain these invertebrates, as many do not contain the optimal climatological conditions required by these organisms. Neither the botanical and faunal survey nor the invertebrate survey revealed any evidence of lava tubes or caves on the property, and no such features have been reported for the area near the Hawai'i Dairy Farms (HDF) site. Thus no cave invertebrate species will be affected by the dairy farm.

INTRODUCED PREDATOR INSECTS

An invertebrate study of manure-associated insects was conducted for the Draft EIS. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently

present at the HDF site. Pest insects such as flies can negatively impact livestock health and production, and are therefore actively managed to prevent stress and loss of productivity at dairy operations.

At the HDF site, two common flies were identified: the stable fly and the horn fly. Both of these flies are widespread throughout the Hawaiian Islands. The greenbottle fly was reared from manure taken back to a laboratory following the field survey. Additionally, flies known to exist on Kaua'i but not seen at the HDF site during the survey were identified and include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations.

In response to cattle-related insect pests, numerous species known to compete with the pests were introduced to Hawai'i between 1898 and 1982. Twenty species of predators and competitors to the horn fly were successfully established during that period. Cattle egrets break up dung patties while searching for prey, and were introduced to Hawai'i in the late 1950s to control cattle-associated insects. Extensive introduction of dung beetle species resulted in 14 dung beetle species becoming established on Kaua'i.

A healthy population of dung beetles can bury a dung pat in one to three days, which disrupts reproduction of flies such as the stable fly and horn fly. The stable fly requires approximately 21 days within the dung patty for the immature life stage (egg to pupa) to survive; the horn fly takes 10 to 20 days from egg to adult. Incorporation of the manure into the soil profile by dung beetles removes the habitat these flies require to complete their lifecycle. Research shows that 95 percent fewer horn flies emerged from dung patties containing a dung beetle species that has been identified at the HDF site. Proven control methods for the stable fly include parasitic micro-wasps and spreading out manure.

Among the invertebrates previously introduced to Hawai'i to combat livestock-related flies are extremely tiny parasitic wasps that prey on various fly species. The adult wasps could be described as the size of gnat. Using an ovipositor – described by lay people as a "stinger" – the female lays eggs in the larvae or pupa of flies. The male wasp has no such "stinger". See Draft EIS Section 4.11 for a photo providing scale for these tiny, non-stinging wasps.

To minimize potential establishment of pest flies or other insects, food waste generated during the construction phase will be bagged, covered, contained and disposed of in order to limit possible breeding habitat for flies. Inspections of building materials for ants or other insects will be conducted to prevent introduction of new pests to the HDF site. Short-term controls, including mechanical methods (e.g. sticky tapes or ribbons in the milking parlor, or traps with or without attractants) and chemical methods may be used to prevent short-term spikes in pest populations.

Insecticides and herbicides are non-discriminatory and kill beneficial as well as pest insects. Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Should chemical control be needed for short-term spikes in pest populations, application would be by those qualified, and

in accordance with regulatory labeling requirements. HDF will implement long-term integrated pest management, which utilizes knowledge of the ancient food web among species by disrupting the manure habitat required to complete the fly life cycle. HDF and other ranchers on Kaua'i may choose to engage with the State Department of Agriculture to translocate dung beetle species already introduced on Kaua'i to Māhā'ulepū and other areas where manure-related flies may be a problem.

IMPACT OF SPRAYS ON BEES

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Honey bees are an essential part of any agricultural ecosystem, and were observed on site during the invertebrate species survey. Pesticides and herbicides can reduce populations of beneficial insects, which is why HDF will utilize an integrated pest management approach.

It is expected that honey bees will visit water sources set up for the HDF herd. Preventative measures will be built into any open water source to prevent bees from being trapped, and HDF will contact local beekeepers for advice regarding any bees or bee colonies encountered on site. Safe application practices for any unavoidable herbicide or pesticide will be utilized in order to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself, a local beekeeper will be contacted for advice and removal.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in BIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.1.1. The project location does not provide any habitat for *Drosophila melanogaster*, the only Kaua'i species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-'ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōloa and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plascch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of

milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with

alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction

Stormwater General Permit Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways;

only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waioipili Ditch provides the majority of freshwater input in the immediate coastal

area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-

Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2), grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000

galbans of the fresh milk demand, reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEFOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner

manure load and has a high potential for runoff.

DRINKING WATER WELLS

HDF should be required to do an extensive groundwater study to assess effects of waste applied to the soil. Their current Waste Management Plan does not identify all of the nearby drinking water wells and misrepresents the distance of some of those that are identified on the map. Most significantly, one well (Koloa F) is very near to the area in which their wastewater treatment plant will apply the sludge that accumulates in the ponds.

AIRBORNE CONTAMINANTS

HDF plans to spray waste from the effluent ponds on the fields as fertilizer. These spray machines are very tall and with dominant trade winds the possibility of spray affecting homes and businesses downwind is a potential problem. The EIS should address airborne contaminants produced by the dairy and the environmental, health, and social impacts.

SOCIAL CONCERNS

The Mahaulepu area is popular for nature oriented activities and subsistence such as fishing, hiking, beach-going activities, bird watching and more. The EIS must address how these activities would be impacted by environmental effects from a large dairy of this size upstream of the beach-going area.

The Koloa/Poipu area is home to approximately 3,000 residents, all of whom will be downwind of the dairy and thus affected by any airborne contaminants or odor. The area is also one of the top 3 visitor destinations, providing significant income to both County and State through property, TAT, general excise and other taxes. Environmental air, water and vector control concerns from the dairy would reduce property values and make the area less desirable to visitors. The largest private employer for the island is within 2.5 miles of the proposed dairy and a thriving visitor industry encompasses the entire Koloa/Poipu area, a decrease in visitors to the area would adversely affect those employers thus causing loss of jobs and income for island residents. Reduced property values and visitors to the area would not only affect the local economy through loss of jobs/decreased incomes for residents, but reduced revenues for the State and County as well.

The above noted concerns should all be fully addressed by the EIS for Hawaii Dairy Farm's proposal at Mahaulepu Valley. Given the open, available, leasable land on the island, particularly that owned by Lessor Grove Farm, this seems to be one of the most ill-suited locations for such an operation. It's proximity to freshwater sources, the ocean, nearby homes and businesses make this an extremely poor

From: Lisa Hechtman
To: HDF
Subject: Comments on Hawaii Dairy Farm's EISPN
Date: Monday, February 23, 2015 12:38:38 PM

Aloha,

I have very serious concerns about the proposed dairy at Mahaulepu Valley on Kauai. I am glad that an EIS will be prepared and hope that it will address the many issues, environmental, social and cultural, that a dairy in this location presents. While HDF states they are voluntarily doing this process, to truly be pono, this should have been done well in advance of any infrastructure changes or the announcement that a dairy IS going in at this location, as the EIS is designed to determine whether a project like a dairy *should* go in by providing substantive data that indicates that it will not be environmentally, culturally or socially harmful.

NUMBERS

Beginning with the proposed herd and the recent "reduction" in herd size to 699 (a significantly chosen number as 700 cows is classified as a Large Confined Animal Feed Operation). What is not noted by HDF with this revised herd size is that those 699 cows will be shipped in pregnant, thus there will be double that number after gestation. Males will then be thinned out through outsourcing and killing of a certain amount, so that 699 would be about 900 cows on the land after gestation. Regardless of this claim of a reduced herd size, the EIS must evaluate the plan based on the proposed final herd size of 2,000.

WASTE

According to the EPA, waste estimates for dairy cattle are equivalent to 164 times the amount of humans, thus the 2,000 cows would produce waste equivalent to approximately 328,000 people, fully 5 times the population of the entire island. Microorganisms causing health risks to humans like E. Coli, enterococcus and leptospirosis are common in the feces of cattle, these organisms could likely end up in the adjacent streams leading to the ocean as well as groundwater.

SOIL

HDF should be required to do a detailed, accurate soil survey to determine once and for all if the soil is able to handle the amount of waste that will accumulate and be applied via airborne spray as fertilizer. Again, had HDF followed proper protocol and done an EIS at the outset, perhaps they would have provided more accurate information on the soil in the area in question. Their initial plan stated that soil in the area was porous volcanic, which it is not. A later NRCS survey of the soil indicates that most of it is primarily clay with "very limited" capability to handle

location for a dairy, especially given that all milk will have to be trucked to the port in Nawiliwili for shipment to Oahu for processing. The above noted environmental, health & social concerns in addition to this fact, render this a plan that will negatively impact the environment and economy of Kauai.

Mahalo for your careful consideration of my concerns and your diligence in evaluating the impacts of this project.

Dear Lisa Hartman:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations

(CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the

cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and

other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversity to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luualaei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasech Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered

volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well

water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs

from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; any irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations

were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area

leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.1.9.2 and 4.2.5.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Subject: Hawaii Dairy Farms Comments

Received a verbal comment from Alfred P. Havas from Arizona who owns property in Koloa, parcel #901. If you want to check with the GM of Poipu Kai, Carolyn, you can verify that he is a property owner. He is disabled and bought into this luxury area, where he feels a dairy doesn't belong here, maybe somewhere else.

Dear Alfred P. Havas:
 Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

Your comments were received by the State of Hawai'i Department of Health Environmental Planning office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

LAND USE: The historical and existing land uses of the project site and surrounding Māhā'ulepū Valley were examined in the Draft Environmental Impact Statement (EIS), and uses proposed by the Hawai'i Dairy Farms (HDF) project were evaluated in the context of county and state land use designations for the area. The evaluation of land use is presented in Draft EIS Chapter 4-4, and the project's consistency with government plans and policies is presented in Draft EIS Chapter 5-0.

Alfred P. Havas
May 26, 2016
Page 2 of 3

The south shore of Kaua'i is home to some of the most productive farm land in the state, attributed to consistent sunshine, ample fresh water, and a large amount of Class A and B soils (with "A" representing the class of highest productivity soils and "E" representing the lowest). The large tracts of farmland, including those of Mahaulepu Farm and Grove Farm, allow for stability in support of farm ventures, help maintain regional water systems and provide agricultural employment for Kaua'i residents in addition to fresh, local food.

The project site is on agricultural land in Maha'ulepu Valley, an area with a long history of agricultural use as it was the first place in the island chain where sugarcane was commercially grown. The site is in the Agricultural District per State Land Use District designations, and per the County of Kaua'i zoning ordinance. The site consists of land classified as Prime per the State Department of Agriculture's Agricultural Lands of Importance to the State of Hawai'i (ALISH). The HDF site is outside of the County-designated Special Management Area under the Coastal Zone Management Program.

In 2005, the State established Important Agricultural Lands (IAL) by statute. The purpose of IAL is to conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands. The designation process determines land meet physical requirements including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with high quality soil agricultural productivity ratings under the Land Study Bureau of University of Hawai'i.

In 2011, Mahaulepu Farm LLC filed a petition with the State of Hawai'i Land Use Commission to designate 1,533 acres of agricultural lands in Maha'ulepu (including 557 acres that make up the HDF site) as IAL. IAL designation meets the objectives of the State HRS §205-42 by contributing to the maintenance of a strategic agricultural land resource base to support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities. See Figure 4.4-2 in DEIS Section 4.4.

The designation process determined that the land meets a number of physical requirements established in HRS §205-45, including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with 88.5 percent of the area featuring an overall soil agricultural productivity rating of "B" per criteria established by the Land Study Bureau of University of Hawai'i.

The development and long-term operation of HDF will be in full compliance with its agricultural State Land Use District designation, ALISH classifications, and County zoning. The dairy farm will embody the intent of the IAL designation per the Hawai'i State Constitution, by using these protected lands for the intended purpose of diversified agriculture, food production and agricultural self-sufficiency. HDF development of a dairy also supports the "secondary intent" for lands in the Agriculture land designation, to provide an opportunity for Kaua'i citizens to reside

Alfred P. Havas
May 26, 2016
Page 3 of 3

in an agricultural community. This is in contrast to the described "agricultural subdivisions" that have changed parts of Kaua'i intended for a rural landscape, with development as quasi-suburban landscapes dotted with residences on large lots.

Overall, the project provides long-term benefit and support of agricultural lands and industry through continued use in keeping with zoning and IAL designation. Long-term operation of the dairy does not preclude the region for future protection in a coastal park at Maha'ulepu.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

GROUP 70 INTL

19 February 2015

To: Ms. Laura McIntyre, Environmental Planning Office, Hawaii Dept. of Health,
1250 Punchbowl Street, Honolulu, HI 96813
cc. Group 70 International, Inc., 925 Bethel Street, 5th Floor,
Hawaii Dairy Farms, LLC
From: Donald E. Heacock, Aquatic Biologist

Hawaii Dairy Farms (HDF) proposes to establish and operate the first zero-discharge dairy in Hawaii using sustainable farming methods on 578 acres of land in Maha'ulepu, Kauai.

General Comments:

- The HDF, as planned, is extremely unlikely to establish a zero-discharge dairy at this site in Maha'ulepu, Kauai, for the following reasons:
- Lack of appurtenant water rights,
 - Located primarily (65%) on soils classified as "hard clay, impervious to water",
 - Located adjacent to streams and Class A marine waters along the Mahaulepu coastline that is classified as Class 1 critical habitat for Hawaiian monk seals, seabirds and green sea turtles that live there,
 - Receiving waters that are already polluted (with indicator bacteria and Nitrogen/Nitrate) as compared to Hawaii's Water Quality Standards,
 - No mitigation plan: if something goes wrong, like thousands of gallons of manure/urine discharged into the ocean, the cumulative and negative impacts on public trust resources (like coral reefs), which may never recover;

Specific Comments/Recommendations:

1) Lack of Appurtenant Water Rights

The proposed HDF is dependent upon Grove Farm supplying them with irrigation water from Waita Reservoir; Waita Reservoir is dependent upon water diverted from the Huleia River by Grove Farm. However, neither HDF nor Grove Farm have appurtenant water rights to water from the Huleia River. The water now being diverted from the Huleia River to fill Waita Reservoir results in the complete dewatering of the river (i.e., dry river bed below the diversion for 100-200 yards downstream), which blocks the migration of native Hawaiian stream animals which need to migrate upstream to their adult habitat, and downstream to spawn; 90% of native Hawaiian stream animals ('o'opu, 'opae and hihiiwai) are endemic, found nowhere else on Earth, furthermore, this severe dewatering of the Huleia River and its negative biological impacts, it is in violation of the Federal Clean Water Act (which requires the protection of the biological integrity of water bodies) and is contrary to the Hawaii State Water Code which is to protect the beneficial instream uses (such as production of fish and wildlife, swimming, aesthetic enjoyment).

Also a local group of native Hawaiians, taro farmers and Kuleana land owners have formed "Hui Ho'opulapula Na Wai o Puna" (lit. the people who want to restore the waters of Puna) to restore the instream flows of the Huleia.

Hanamaulu, Wailua and other rivers and streams in the Puna District. The Hui is working with Earth Justice and will petition the State Commission on Water Resources Management (CWRM) to establish the Hanamaulu Aquifer (which includes the Huleia River to the South fork of the Wailua River) as a "Ground and Surface Water Management Area") and to restore instream flows to the streams and rivers within the Hanamaulu Aquifer. Because of presidents set in previous Hawaii Supreme Court Decisions and Orders (Waiahole, 2000 and Na Wai Eha (2014), the outcome of the Hui's petition to CWRM can legally be determined.

Recommendation: Therefore, the EIS should include specific data/documentation establishing Grove Farm's and HDF's having appurtenant water rights to the water of the Huleia River for public trust beneficial uses.

2) Coastal Receiving Waters Already Polluted

Currently, according to water quality monitoring data collected by Dr. Carl Berg, Surfrider Foundation, Kauai Chapter, the nearby receiving waters are polluted far beyond the Hawaii Water Quality Standards with indicator bacteria and with nitrogen/nitrate. Therefore, any polluted storm water runoff from the proposed HDF site will further and cumulatively negatively impact coastal water quality, the coral reef ecosystem, and other public trust natural resources.

Because the recently conducted USDA/NRCS¹ detailed soil analysis of the HDF site, showing that the dairy site is composed primarily (65%) of hard clay soils impervious to water (which HDF neglected to cite/mention in their Farm Conservation Plan), it will be virtually impossible to prevent polluted runoff from the HDF site with such high cow stocking rates during periods of heavy rains. These discharges will cumulatively add to coastal eutrophication, coral reef degradation and to losses of public trust natural resources.

Recommendation: Therefore, with these points in mind, and based upon the Precautionary Principle, no NPDES permits should be issued until the existing water pollution in the area is cleaned up, and additionally, until HDF shows conclusively that they can prevent storm water discharges containing pollutants from the dairy.

Sincerely,
Donald E. Heacock

Donald E. Heacock, Aquatic Biologist

¹ USDA/NRCS. 2014. Custom Soil Resource Report for Maha'ulepu, Kauai. Pp. 1-78

grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrates to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either near-shore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili Ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (<http://health.hawaii.gov/cwb/>).

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

Donald E. Heacock
May 26, 2016
Page 5 of 6

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

MITIGATION

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that

Donald E. Heacock
May 26, 2016
Page 6 of 6

could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

The potential for environmental accidents at the dairy farm will be minimal. Reviews and approvals are required from the State Department of Health for the waste management facilities. Standards and regulatory requirements must be met, and capacity beyond the required volumes has been added to provide additional backup storage. A secondary containment system has been designed as an additional safeguard. Risks to surface water quality are minimized with application of best management practices including vegetated buffer zones and 35-foot setbacks to exclude cows from farm drainageways. Effluent irrigation will not occur within 50 feet of agricultural ditches on the farm. Fuels and chemicals utilized at the dairy facilities will be used and stored following established rules and protocols.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Maha'ulepu valley

Dear ms. McIntyre,

As a resident of the poiipu area of kauai, I have been keeping abreast of the status of the dairy farm proposed for maha'ulepu valley. My understanding is that an environmental impact study will be prepared.

Giving the controversial nature of the impact of the dairy on the residents in nearby communities, it would appear to me that having that effort lead by group 70 would be a serious conflict of interest. In this case we are basically asking the fox to tell us about the hen house. Without a clearly independent eis the controversy will be more pronounced should the results favor the building of the dairy.

The governmental agencies should require that the people who prepare the eis statement not favor one side or the other.

There are many simple ways to assure the independence of the process. Let the developers pick an expert, and those in the community who object to the location pick an expert. Those two people can then pick a professional who is truly independent.

The resulting eis statement would then have the support of both constituencies, or at worst the independence of the statement would not be called into question.

Very truly yours,

John t. Healy

Dear John T. Healy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The Environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner

An Environmental Impact Statement (EIS) is being prepared voluntarily by the Applicant to assess potential environmental impacts and mitigation measures associated with agricultural operations at Hawai'i Dairy Farms (HDF) at Māhā'ulepū, Kaua'i.

To assist in preparing the EIS, an Environmental Impact Statement Preparation Notice (EISP/N) was recently published. A 30-day public comment period on the EISP/N ends February 23, 2015. The purposes of the publication and comment period are two-fold:

1. to allow individuals and groups to request to become a consulted party; and
2. to provide written comment regarding effects of the proposed action.

NOTE: Submitted comments will be published in the Draft EIS

Comments: I am opposed to the establishment of a large dairy farm in the Keolu / Rapii / Mahalepu locale. Although I am an avid supporter of agriculture I believe the siting of a dairy in that area is inappropriate. The risks of erosion mented polution is too great regardless of the technical advancement in dairy farming. Such a project is incompatible with the cultural and archeological heritage of the site. Large concentration of dairy cows will bring flies requiring residents to use pesticides for control. Trade winds being stent to the resident of a resort areas. In spite of all the manure and nitrate problem the city still proposes to use manure fertilizer for "sustainability". I think this is a good project but aimed at the wrong site. A more appropriate area would be the former moai come lands by Ketaka Sugar - owned from the state - now 'idle'.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Stephen Hee:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-

Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered projects, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the

HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.1.1. The project location does not provide any habitat for *Drosophila musaphilia*, the only Kaua'i species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ohi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōka-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōka and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035; when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top

of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure

application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be

dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid,

reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

We are fortunate to live on the beautiful island of Kauai on a part-time basis, 4 months a year. We have been coming here for over 20 years, and truly believe this is one of the most beautiful places to be.

It is greatly distressing to us to hear about the proposed dairy farm on the Mahaulepu site in Poipu. This is such a pristine site and includes many archeological sites and sacred grounds for the Hawaiian people. These areas have been protected for hundreds of years, and now could be destroyed with the dairy farm operation. It may not be a direct destruction, but the volume of cow manure produced in such a small area has to go somewhere, and the many beautiful sites here are the ones at risk for run off and contamination.

There is already water pollution in the area from the local stream, and they still can't determine where it originates. What will occur if you had thousands of pounds of cow manure? There is not a holding tank that could contain the volume, especially in the heavy rains that occur in the area on a periodic basis. The fragile ecosystem we have will be eliminated, and there are many people who enjoy the tidepools and other areas on a daily basis who will no longer have the experience.

Currently, tourism is the major industry on this beautiful island, with the Poipu area being a major draw with the fine hotels and accommodations available. We are home to several great beaches, as well as top notch restaurants and shops. I can't imagine anyone wanting to spend time in paradise smelling cows and swatting flies while sitting on a beach when there are so many other options to choose from. It is amazing how the crowds have increased over the years we have been coming here, and that is a positive for Kauai and the economy.

We do not want to see our beautiful Poipu area destroyed by this dairy farm. There are many acres of other sites on the island that would be a better locale for such an endeavor—why not start with the former dairy farm that was destroyed in the hurricane by Anahola?

Please do not let this farm proceed in Mahaulepu, and protect our home and place in paradise.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Gary and Jackie Heinen:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau,

and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plach Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the

development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E

and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane

plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauai region (the Kōloa - Po'ipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running

through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or

maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainage ways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainage ways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater

and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food

production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.

- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kauai, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

FEB 24 2015
GROUP 70 INTL

These are my concerns that need to be addressed and answered by the EIS (Environmental Impact Statement) for this Dairy farm.

First, why is the same company (Group 70 International) that designed the buildings and waste pools for this Dairy handling this EIS. Why is it not an independent 3rd party that specializes in doing EIS studies?

The HDF (Hawaii Dairy Farm, LLC) independently modified the design of the effluent ponds after having received additional rainfall data and as a result of a "collaborative effort" with the community and the DOH. But why was the initial plan for the ponds was submitted without adequate soil analysis and without accurate storm data or rainfall readings?

Why did HDF exclude the results of the "Custom Soil Resource Study" done by the Natural Resource Conservation Service when it filed its current Waste Management Plan with the state on July 23, 2014? The study, released June 5, 2014, focused on the proposed dairy site and concluded that HDF's plan for a land application of the cow waste would be problematic at Māhāulepū, as more than 50% of the proposed farm soil is at high or very high risk of runoff due to its high clay content.

Why such a large operation (one that won't even keep its milk on this island), when a much smaller and truly self-sustaining dairy could be located in many other sites within Grove Farms vast holdings and actually be a successful (& Environmentally sound) operation. Are the principles in this operation just looking to fail for some needed Tax Write-Offs???

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhāulepū Road
Kauai, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Larry Heller:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawaii Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawaii Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawaii Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawaii Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhāulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and

irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kālihi Clay at 32 percent, Kā'ena Clay Brown Variant at 29 percent, and Luālualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of

soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kālāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore

recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to

increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and

neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the

agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i

TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Tom and Ann Hennessy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

GROUP 70 INTL

Dear Planning Staff members:

Thanks for the opportunity to submit our questions as part of the Maha'ulepu Dairy EIS process. We are homeowners in Koloa but also own two homes in the Southland region of New Zealand. We have seen the impact of the "white miracle" on Southland waterways. Once renowned for its fly fishing rivers and streams, New Zealand now finds many waterways in Southland polluted and clogged with "didymo" (footnote 1), making proximity to waterways unpleasant and unsuitable for recreation because of the unpleasant odor and appearance. The spread of didymo coincided with the spread of industrial dairies.

In New Zealand, the main problem seems to be that, even though there are regulations governing water pollution, there is lack of enforcement. This is an ongoing issue in normal times, but in times of extreme weather the problem is chronic. 6 months ago, heavier than normal rainfall led to the relaxation of what environmental standards did exist, allowing farmers to release toxic effluent from their ponds to avoid complete collapse of their reinforcing structures (footnote 2).

So, we have three questions. First – what regulations are in effect to govern water quality, who will enforce them and does that agency have sufficient resources to ensure that regulations are not breached?

Second, what provisions are going to be made to for extreme weather events?

Third, why does this project have to be placed near an area that is so important for tourism, which provides so many jobs and contributes so much to the economy? Pollution will certainly impact the number of tourism jobs on the South Shore and provide few jobs in return. In New Zealand, industrial dairy positions are usually filled by migrant workers because they are so unpleasant that New Zealanders do not want them.

Best regards,

Tom and Ann Hennessy

- 2. <https://agrihq.co.nz/article/effluent-exemptions-for-southland-dairy-farmers?#p=11>

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasz Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix I.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauai region (the Kōloa - Po'ipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part 1 of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part 1*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top

of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure

application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be

Tom and Ann Hennessy
May 26, 2016
Page 10 of 10

dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.1.9.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population and approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawaii Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTL

February 23, 2015

Dear Planning Staff members:

Most people on Kauai support agriculture if it is done right. If you really want to have a farm and you really want the support of the citizens, create a model that does not pollute the aquifer, does not use artificial chemical fertilizers, does not use GMO feed, and is sustainable. I would suggest an organic grass fed only beef cattle farm which puts the correct amount of animals on the land that the land can support. The beef would be in high demand for local residents who would be proud to support such a venture.

The idea of an intensive dairy operation producing excessive amounts of effluent and using chemical fertilizers that pollute the aquifer, streams, beaches and coral is something that many community members cannot support. The importation of GMO feed is questionable. Water pollution and the use of non-indigenous insects to control the flies would adversely affect the tourism industry and businesses and jobs in the Poipu area.

The obvious choice for Grove Farm is to work with the community and be a hero.

Best regards,

Tom Hennessy

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Tom Hennessy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRC's, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Placch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix I.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035; when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy watershed, DOH conducted a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top

of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure

application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be

dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Subject: HDF Dairy Farm on Koloa in the Maha'ulepua Area.

To whom it may concern:

I am opposed to the subject dairy farm due to its effect on air quality in the area in which I live, namely the POIPU area south of Koloa. Because of my proximity to dairy farms where I have previously resided, I am acutely aware of the effect on air quality of effluent holding ponds on areas downwind from the farm. In the case of HDF, we are located directly downwind from this facility due to the prevailing trade winds common to this area. Regardless of the feeding process of this proposed dairy farm, the milking area generates large quantities of foul odor waste due to cattle elimination waste and the water used to remove it from the milking area.

Without highly effective water treatment facilities it will be impossible to control the odor emanating from this area. I question whether studies concerning the holding area for waste consider guarding against rains of the magnitude of those received by this area during March of 2006 amounting to approximately 40 inches for the month.

Your thoughtful consideration of these concerns will be greatly appreciated.

Sincerely yours,

Herbert F Herndon,
1901 Poipu RD #232

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Herb Herndon:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths - as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain

by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 - 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 - 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction

Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways;

only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waioipili Ditch provides the majority of freshwater input in the immediate coastal

area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM_{10} and $PM_{2.5}$) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM_{10} is $2.01 \mu\text{g}/\text{m}^3$, well below the State standard of $150 \mu\text{g}/\text{m}^3$. The estimated concentration for $PM_{2.5}$ is $0.23 \mu\text{g}/\text{m}^3$, well below the Federal standard of $35 \mu\text{g}/\text{m}^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://hinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: HDF in Mahaulepu Area, Kauai

To whom it may concern:

I am opposed to the proposed dairy farm in the Mahaulepu Area, Kauai due to its effect on air quality in the area in which I live, the POIPU area south of Koloa. Because of my proximity to dairy farms where I have previously resided, I am acutely aware of the effect on air quality of effluent holding ponds on areas downwind from the farm. In the case of HDF, we are located directly downwind from this facility due to the prevailing trade winds common to this area. Regardless of the feeding process of this proposed dairy farm, the milking area generates large quantities of foul odor waste due to cattle elimination waste and the water used to remove it from the milking area.

Without highly effective water treatment facilities it will be impossible to control the odor emitting from this area. I question whether studies concerning the holding area for waste consider guarding against rains of the magnitude of those received by this area during March of 2006, amounting to approximately 40 inches for the month.

Your thoughtful consideration of these concerns will be greatly appreciated.

Sincerely yours,

Joyce W. Herndon

Dear Joyce Herndon:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

Your comments were received by the State of Hawai'i Department of Health Environmental Planning office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas

determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaaui and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaaui has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhāulepū region during and following the hurricanes that affected Kaaui in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhāulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaaui over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhāulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhāulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035; when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top

of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure

application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be

dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUA1>

Thank you for your participation in the environmental review process.

Sincerely,

Is Mahau'lepu a Particular* Landfill?

Prior to any approval from government agencies allowing the Mahau'lepu area to be used as a site for a possible health hazard / water polluting dairy farm, or any other agricultural endeavors, this Kauai resident recommends that an "independent civil investigation" be conducted concerning the possibility that environmental violations have occurred in the above mentioned area resulting in the creation of a clandestine "Solid Waste Disposal Facility"; commonly referred to as a "landfill".

Over the past decade and a half, both private (business) and public (government) sector's records indicate evidence that certain solid waste materials, namely Construction & Demolition debris (C&D) along with hazardous waste (asbestos & red lead paint), have been disposed of in un-supervised fashions.

Such acts of possible circumvention of legitimate, best industry practices, are considered crimes; both civil and criminal, and need to be clarified. Why add more possible pollutants to an area that may already be polluted? Let's find the truth.

Not only does it create the possibility of exposing the Poipu - Koloa - Mahau'lepu area residents, vacationers, businesses, schoolsour children.... to health and life threatening issues, such actions also deprives our County of Kauai much needed revenues generated from tipping fees which support our government and our island. ALOHA

John Hoff

Environmental Impact Statement Preparation Notice
Mahā'ulepū Road
Kauai, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear John R. Hoff:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Mahā'ulepū Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S.

Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The

management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of

soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kālāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makuawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore

recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands. Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to

John R. Hoff
May 26, 2016
Page 8 of 9

increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

John R. Hoff
May 26, 2016
Page 9 of 9

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

GROUP 70 INTL

To Whom It May Concern:

My name is Maureen Holt. My husband Howard and I founded Trustile Doors Inc. in Denver Colorado in 1995. Trustile is an MDF door manufacturer. MDF is a product made from wood dust and compressed into sheets that are cut and styled into doors. It is an environmentally green product. We built a state of the art 50,000 square foot plant and we burned our waste to create the energy we needed to run our equipment. The air quality leaving our plant was actually cleaner than the air coming into our facility. We provided a safe workplace and created 168 American jobs. We sold our company and in 2006 we moved to Kauai.

We had vacationed in Kauai 7 different times before the actual move. We loved Kauai for its weather, natural beauty, and its life style. We purchased a home in Koloa Estates on the South Shore of Kauai near the world famous Poipu Beach. The air and water quality are much better here than that of the mainland Howard breathes easier here and doesn't have to take as much medication for his Asthma. The warm weather is easier on me with my arthritis and lower back pain. It is a great place to live. We spend most of our time outdoors while our friends and family on the mainland have to live indoors during the cold winters.

We are extremely concerned about an industrial sized dairy coming to our island. On the mainland dairies are usually located off busy highways on huge parcels of land away from housing developments and pristine coastlines. We have driven by dairy farms and had to hold our breath due to the odor caused. Dairies are notorious for bringing in flies. One expert that happens to live on the north shore of Kauai stated there would be one billion flies. The odor and the flies would ruin our quality of life here. We like to eat outside, enjoy swimming in our pool, gardening and playing Frisbee with our labradoodle Rosie. We will have to invest in expensive air conditioning instead of enjoying the cool trade winds and shut our windows to avoid the odor and the constant buzzing and biting flies. It is estimated that our property values could drop as much as 40% which would affect the property tax revenue base for the county. Our house is paid in full and we would have to walk away from our investment, most people have loans and would walk away from what they paid leaving the bank their home.

The dairy is only going to create 15 jobs and it has the potential to completely destroy tourism on our beautiful South Shore. Tourists are not going to spend all the money it takes to get here to smell cow dung and sweat flies. The amount of jobs lost if tourism drops could be in the thousands. Kauai depends on tourism for its sustainability. The Grand Hyatt hotel has filed a lawsuit against the dairy. The Hyatt has already lost business since conventions are booked years in advance and just the idea of an industrial sized dairy coming in such close proximity to the Hyatt has caused businesses to find

other locations for their conventions. The Hyatt was planning to expand its location to add more hotel rooms to the south shore which would create more jobs for the largest employer on the island. The Hyatt is a good steward of the land and keeps the grounds very pristine and welcoming, and is an excellent company to work for. Our son works for the Hyatt in Beaver Creek Co. and he loves his job.

The Hawaiian people want to be good stewards of the land their "aina, honua" and keep it for future generations. There are several significant sites that are considered sacred and need to be undisturbed by the dairy. The waste caused from the dairy could destroy already endangered plants, birds, coral and several species of ocean life.

We are concerned about the dairy location only 750 feet from our wells for our drinking water. We feel the amount of waste generated by the industrial dairy will make our drinking water unsafe, due to the large amount of urine and manure left on the grazing land.

The dairy is modeled after dairies in New Zealand and we just need to look to what has happened there and realize this is not right for Kauai. The beaches there are not black sand they are black from manure deposits with swimming and fishing becoming a thing of the past.

Dr. Carl Berg of Surf Rider has tested the water quality and it is already polluted with human and animal waste and the Department of Health agrees with their findings. We need to find the sources of the pollutants and see that Steve Case the owner Grove Farm cleans up the water prior to a dairy being established on the site. The Friends of Maha'ulepu offered to put up signs on the beaches to discourage swimming in the polluted water and Grove Farm refused to post the signs. They don't want to discourage tourism, however there is a health risk associated with swimming in the polluted water.

We believe in the American dream and Peter Omidyar created a great thing with EBAY. We as previous business owners commend him on his success; however leasing the land from Grove Farm to build and industrial sized dairy is a really bad idea for Kauai. Peter needs to create jobs at the same time take care of the environment and not affect surrounding communities. His legacy should be to improve the quality of life here on the island.

We want to trust that our government officials will protect us against the damaging effects this dairy will cause our island. We believe the Environmental Impact Study will prove that this site is unsuitable for and industrial sized dairy. We are so blessed to live in such a desirable place, let's keep it that way for future generations.

Sincerely,

Howard F. & Maureen C. Holt

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4)2-9-003:001 portion and 006 portion
(4)2-9-001:001 portion

Dear Howard & Maureen Holt:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex

were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawaii's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kauai but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila musaphilia*, the only Kauai species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhri'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōba-Poi'pū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōloa and Poi'pū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Placch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of

milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with

alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauai region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hatupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction

Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways;

only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal

area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kāua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of the panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Howard & Maureen Holt
May 26, 2016
Page 15 of 15

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawaii Dairy Farms": <http://hivyaui.com/OEQCKAUAU>

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Hawaii Dairy Farms

Dear Sir

I am a property owner in the Poipu, Kauai area and am concerned about, and opposed to, the proposed dairy farm at Mahaulepu. I was unable to attend the HDF meeting in Koloa Thursday but read the covering article in the Garden Island newspaper today which included a statement by Jeff Overton of Group 70 International. The statement " This project is really about food sustainability..." puts in doubt the objectivity of any EIS conducted by Group 70 International. The EIS is really about the environment, not food sustainability! I have visited friends in Lynden and Carnation, Washington and I can assure you the aroma is not pleasant for miles around, as well as whatever other negative environmental impact may be present. I am in hope that after the year involved in preparing the EIS, you too will feel this is an ill advised project

Thank you

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Mahā'ulepū Road
Kaua'i, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Jens Houby:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawaii Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawaii Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawaii Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawaii Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's

Jens Houby
May 26, 2016
Page 2 of 4

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawaii Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy

cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM_{10} is $2.01 \mu\text{g}/\text{m}^3$, well below the State standard of $150 \mu\text{g}/\text{m}^3$. The estimated concentration for $PM_{2.5}$ is $0.23 \mu\text{g}/\text{m}^3$, well below the Federal standard of $35 \mu\text{g}/\text{m}^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Re: Hawaii Dairy Farms Environmental Impact Statement

Dear Mr. Overton,

My wife and I reside in Poipu, Kauai, approximately 6 months out of the year and we want to provide our deepest concerns regarding the Hawaii Dairy Farm (HDF) proposed for construction in the pristine area of Mahalepu located in the SE coastal area of Kauai County.

While we realize that Hawaii desires additional economic drivers for its economy, this cannot come at the certain degradation to its environment and protected wildlife. This is particularly true when the benefits are miniscule as compared to the considerable negative impacts this non-critical business venture would certainly bring to this beautiful and highly regarded tourist and resort area of Poipu.

We are asking that the Hawaii Department of Environmental Protection and the Hawaii Department of Health thoroughly evaluate and at a minimum require very strict stipulations for this operation.

As to how this operation would negatively impact us personally and directly (and others like us) is the high probability of it causing health issues. Both my wife and I are retired and she has an impaired immune system that makes her highly susceptible to infections - particularly sinus

infections. The reason we purchased a home in Kauai (and Poipu in particular) is its pristine conditions - most notably its air. The location of a potentially high density dairy operation less than 3 miles upwind of our home would create a host of health issues for people with upper respiratory and sinus conditions that visit here for the benefits of breathing pristine salt air carried in by the prevailing northeasterly trade winds. These trade winds travel thousands of miles unencumbered by human interference and pollution. These conditions would be considerably degraded and in our case could lead to my wife catching infection from microscopic particles carried in on the trade winds from the dairy. If this happens we will be forced to try and sell our property (no doubt it will be worth less than we paid for it 10 years ago) and relocate to another area. Because we are retired and planning to spend more time in Kauai, the fate of this HDF will have a significant impact on our future plans as well as the well-being of my wife. My wife's infectious disease doctor in Denver (as well as her ear, nose, and throat doctor) recommends that we consider living in Poipu full time due to its pristine conditions and the noticeable improvements in her health when we are on Kauai.

We have spent most of our adult lives in the Denver metropolitan area and even though we are over 50 miles away from similar dairies as the proposed HDF, when the wind shifts to the NE the odors from the dairies are overpowering even in Denver. I personally spent 2 decades working on projects close to several dairies in Weld County (that I will not name), but several are located near Platteville, CO. I can say firsthand that the stench from the dairies on certain days was overpowering. Those days (fresh rain, high humidity, and warm temperatures) made working near the dairy unbearable. While these conditions are few in number in the high arid conditions of Colorado, they are an everyday occurrence at the proposed site in Mahalepu. I will barely address the proliferation of insects at dairies in Colorado except to say, when working near the dairies my crew and I could not eat within a mile of the facility without sitting in our trucks with the windows rolled up and the air conditioning on or otherwise

daily hatching flies fresh from eating manure and feasting on the green slime of the catch ponds would invade us and land on our lunches making them inedible. Conversely, people (residents and tourists) come to Poipu to eat fresh seafood outside and enjoy the views and smell of gardens and the salt air....NOT the stench from the catch ponds at the proposed dairy and be continually irritated and potentially harmed by disease carrying flies (and mosquitos as well).

The bottom line is unlike the pastoral setting of cows grazing in a field that Group 70 purposefully put on the cover of their document to present a perceived peaceful ambience for their project, a working dairy is a dirty, smelly, disease ridden place where crews wear knee high rubber boots, arm length rubber gloves, walk around in ankle deep filthy sludge and wear masks to protect their lungs as it is a very unhealthy place to be around or even be near. Dairies should not be positioned near any populated area as many studies have shown. We would respectfully ask the DOH and HEPA to consider these issues as well as several other points that were glossed over or completely ignored in the preliminary document provided by Group

70 regarding the proposed HDF:

1. Soil conditions - as a licensed engineer with a minor in geology and 40 years working with geologists I can say that soil conditions in any large area is highly variable and is certainly not homogenous. Therefore, we would request that a more thorough and rigorous soil analysis be performed of the dairy site including multiple soil samples taken at various depths in a multitude of areas before reaching any conclusion about whether or not the soil would have enough permeability to transmit effluent urine and feces residue down to groundwater. In an area of 570+ acres there will no doubt be areas where the clay content is limited to minimal and will allow percolation of contaminated fluids into the groundwater. But at the same time, high clay content in other areas will

hold fluid and result in significant run off of fluids downslope to the ocean. What will be the plans to prevent this and what is the penalty when this inevitably occurs? Pay a fine for continuing to pollute?

2. Along the same vein, there needs to be a data driven monitoring set of processes to insure no contaminated effluent gets to groundwater such as drilling monitoring wells along the perimeter of the property as well as wells offsetting the "effluent catch basins" to insure they are not leaking. Likewise, the design and construction of these "catch basins" need to be clarified including how (and with what they will be lined) and how much head board (berm) will be included to insure they will not be overrun when extended heavy rains occur.

We are incredulous that there will be county and private potable drinking water wells located within 750' from this operation. A study as to fluid transport through this type of soil has to be required including transmissibility rates and directionality. Potable drinking water on Kauai (as well as the other islands) is priceless...just check ask

Moloka'i.

3. A detailed plan regarding dust particulate mitigation is needed and not just during the construction period. More importantly will be continual mitigation efforts during the permanent operation when equipment is continually moving into and out of the facility relocating cows around the facility, bringing in other needed farming and milking equipment, daily transportation of the milk to its final processing plant. Group 70 did not mention that the limited road infrastructure into this area is all dirt.

4. A detailed cost/benefit analysis is needed to measure the benefits of this dairy (how many actual permanent jobs will be created and expected tax revenues) vs. several scenarios of estimated reductions in tourist traffic (and loss of established permanent jobs to hotels and homes that are seasonal vacation rentals) due to the odors

originating just 2.5 miles upwind of one of the two largest tourist destinations on Kauai. Once word gets out regarding the odor problem in Poipu, the average tourist will choose to spend his/her vacation elsewhere.

5. In addition, a larger and more specific data set should be required regarding current occupancy rates of residences at Poipu. The vague statement that 56.2% of the housing units are vacant does not appear current or factual. How was this one number derived and when/where did it originate?

6. From first hand observation the Hawaiian Monk Seal and Green Sea turtles reside in the waters and beaches $\frac{1}{2}$ mile downslope from this proposed operation. Also, the threatened and endangered (T&E) Humpback whale frequents the waters on this side of Kauai.

These specific animals (along with lots of large sea birds) are seen daily in this area. The EIS needs to provide protection for these sea creatures from any potential damage to their habitat from contaminated run off that could occur during monsoonal rains and floods such as the "40 days of rain" that occurred in the Koloa and Poipu area a few years back. Also protection is needed to prevent birds (particularly T&E fowl) from landing in the filthy and disease ridden "catch basins".

7. It is a faulty argument to equate historic sugar cane production that ended decades ago as equivalent to a high density dairy operation. Tons of sanitary waste (urine and feces) were not created with these operations and the cultural aspects of the area (including the extremely rare Makuuhi Cave) were unknown when these operations began. Now we know that this particular cave is very rare and holds tremendous paleoecological and archaeological data and has been described as "maybe the richest fossil site in the Hawaiian Islands and perhaps in the entire Pacific Island region". The area around this site has been painstakingly improved and is becoming a favorite visiting site for locals and non-locals to visit and learn about the ancient history of this area. This area is

directly offsetting the HDF to the south and will be severely impacted by foul odors emitted from the dairy.

Data is needed in the EIS referencing similar high density dairy operations in a "tropical environment" loaded with cultural artifacts and what measures are needed for a setting such as Mahaulepu Valley.

8. Finally, even though this is referred to as a "zero discharge" facility which sounds nice, but in reality means all the manure and urine stay on-site....that is TONS and TONS of it. As Group 70 boasts the tons of cow manure will be spread throughout the property to fertilize the grass. Assuredly that much manure when it is spread back as fertilizer is quite a large point source of odor. With a little rain, the smell is horrific.

My personal experience from being around dairies is grazing cows (often in groups of 20 or more) urinate and defecate when they feel like and where they feel like it. If you have witnessed cows urinating and defecating first hand, it is not a small volume of urine or feces and certainly not a pleasant event to smell. How will all of this waste be handled? Will it be gathered daily into a pile? What about the urine? All of this will provide opportunity to potentially damage to groundwater in the high percolation areas and, of course, the odor emissions when the herd reaches 2,000 cows will be significant.

While quite a bit of statistical data was included in the notice from the Group 70 regarding the amount of milk that the HDF would produce, nothing was included regarding how much urine, manure, belching and flatulence would be produced daily and the resulting methane (greenhouse gas) that would be released into the atmosphere. Published data support that cows emit a massive amount of methane through belching and flatulence. Statistics vary regarding how much methane the average dairy cow expels but some say it's up to 500 liters (132 gallons) per day or an amount comparable

to the pollution produced by a car in a day. While the Group 70 report refers to HDF using a "smaller" "kiwi cross cow", the difference in size is primarily in height not girth and the weights are nearly identical. The "kiwi cross cow" is a hybrid of a cross breed of Holstein and Jersey cows. Coincidentally, in New Zealand a tax proposal on dairy cow flatulence has been considered and the "kiwi cross" dairy cow is used almost exclusively there. Please note the photo of a herd of "kiwi cross" dairy cows below:

"The large amounts of methane produced by cows are now a cause of concern and the subject of much scientific research. Agriculture is responsible for an estimated 14 percent of the world's greenhouse gases. A significant portion of these emissions come from methane, which, in terms of its contribution to global warming, is 23 times more powerful than carbon dioxide."

Adding in the smell of animal feces especially after it stays wet from daily rains (3-4 small showers a day are common in this area) and this entire area will not be a pleasant to visit nor a place to live. The smells are magnified when the sun comes out and the temperature and humidity rises. The offensive odors will be easily carried by the 15-25 mph trade winds that consistently blow from the NE downwind for miles. The statistics for total waste and methane the cows will generate should be calculated and a plan for its containment and remediation needs to be included in the EIS.

In conclusion, with all due respect to the HEPA and the HDOH, simply requiring "Best Management Practices" as part of the permit approval process will not prevent breaches and lapses in the HDF daily operating practices. One only has to do a case study on permitted facilities to see citation after citation issued for infractions where permit BMP's are continually violated. This often results in protracted legal battles over fault; arguments over the magnitude of the violations; and after much time passes minimal fines are sometimes collected. This does little to correct the environmental damage done. How this will be handled will need to be part of the EIS. A suggestion is that the DOH and HEPA have personnel on island and in the immediate area to monitor the operation and issue citations quickly when infractions occur.....in the real world, self-monitoring and self-reporting simply does not work.

We respectfully ask that all these factors be given serious consideration during the EIS preparation and review process.

Sincerely,

David Howell

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4)2-9-003:001 portion and 006 portion
(4)2-9-001:001 portion

Dear David & Linda Howell:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S.

David & Linda Howell
May 26, 2016
Page 2 of 15

Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The

management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data

the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Ka'ena Clay Brown Variant at 29 percent, and Luualalei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due

to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL. The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities; it is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the

exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasz Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$6,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the

committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic

material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and

visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could

be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwbb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations

were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of the panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

Re: COMMENTS ON HAWAII DAIRY FARM'S ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE, DATED JANUARY, 2015.

Aloha,

I have very serious concerns about the proposed dairy at Mahaulepu Valley on Kauai. I am glad that an EIS will be prepared and hope that it will address the many issues, environmental, social and cultural, that a dairy in this location presents. While HDF states they are voluntarily doing this process, to truly be pono, this should have been done well in advance of any infrastructure changes or the announcement that a dairy IS going in at this location, as the EIS is designed to determine whether a project like a dairy *should* go in by providing substantive data that indicates that it will not be environmentally, culturally or socially harmful.

NUMBERS

Beginning with the proposed herd and the recent "reduction" in herd size to 699 (a significantly chosen number as 700 cows is classified as a Large Confined Animal Feed Operation). What is not noted by HDF with this revised herd size is that those 699 cows will be shipped in pregnant, thus there will be double that number after gestation. Males will then be thinned out through outsourcing and killing of a certain amount, so that 699 would be about 900 cows on the land after gestation. Regardless of this claim of a reduced herd size, the EIS must evaluate the plan based on the proposed final herd size of 2,000.

WASTE

According to the EPA, waste estimates for dairy cattle are equivalent to 164 times the amount of humans, thus the 2,000 cows would produce waste equivalent to approximately 328,000 people, fully 5 times the population of the entire island. Microorganisms causing health risks to humans like E. Coli, enterococcus and leptospirosis are common in the feces of cattle, these organisms could likely end up in the adjacent streams leading to the ocean as well as groundwater.

SOIL

HDF should be required to do a detailed, accurate soil survey to determine once and for all if the soil is able to handle the amount of waste that will accumulate and be applied via airborne spray as fertilizer. Again, had HDF followed proper protocol and done an EIS at the outset, perhaps they would have provided more accurate information on the soil in the area in question. Their initial plan stated that soil in the area was porous volcanic, which it is not. A later NRCS survey of the soil indicates that most of it is primarily clay with "very limited" capability to handle manure load and has a high potential for runoff.

DRINKING WATER WELLS

HDF should be required to do an extensive groundwater study to assess effects of waste applied to the soil. Their current Waste Management Plan does not identify all of the nearby drinking water wells and misrepresents the distance of some of those that are identified on the map. Most significantly, one well (Koloxa F) is very near to the area in which their wastewater treatment

plant will apply the sludge that accumulates in the ponds.

AIRBORNE CONTAMINANTS

HDF plans to spray waste from the effluent ponds on the fields as fertilizer. These spray machines are very tall and with dominant trade winds the possibility of spray affecting homes and businesses downwind is a potential problem. The EIS should address airborne contaminants produced by the dairy and the environmental, health, and social impacts.

SOCIAL CONCERNS

The Mahaulepu area is popular for nature oriented activities and subsistence such as fishing, hiking, beach-going activities, bird watching and more. The EIS must address how these activities would be impacted by environmental effects from a large dairy of this size upstream of the beach-going area.

The Koloa/Poipu area is home to approximately 3,000 residents, all of whom will be downwind of the dairy and thus affected by any airborne contaminants or odor. The area is also one of the top 3 visitor destinations, providing significant income to both County and State through property, TAT, general excise and other taxes. Environmental air, water and vector control concerns from the dairy would reduce property values and make the area less desirable to visitors. The largest private employer for the island is within 2.5 miles of the proposed dairy and a thriving visitor industry encompasses the entire Koloa/Poipu area, a decrease in visitors to the area would adversely affect those employers thus causing loss of jobs and income for island residents. Reduced property values and visitors to the area would not only affect the local economy through loss of jobs/decreased incomes for residents, but reduced revenues for the State and County as well.

The above noted concerns should all be fully addressed by the EIS for Hawaii Dairy Farm's proposal at Mahaulepu Valley. Given the open, available, leasable land on the island, particularly that owned by Ilesor Grove Farm, this seems to be one of the most ill-suited locations for such an operation. Its proximity to freshwater sources, the ocean, nearby homes and businesses make this an extremely poor location for a dairy, especially given that all milk will have to be trucked to the port in Nawiliwili for shipment to Oahu for processing. The above noted environmental, health & social concerns in addition to this fact, render this a plan that will negatively impact the environment and economy of Kauai.

Mahalo for your careful consideration of my concerns and your diligence in evaluating the impacts of this project.

Subject: Hawaii Dairy Farms
 Environmental Impact Statement Preparation Notice
 Māhā'ulepū Road
 Kaua'i, Hawaii
 TMK: (4) 2-9-003: 001 portion and 006 portion
 (4) 2-9-001:001 portion

Dear Marisa Hurley:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP), published January 23, 2015, described the proposed pasture-based rotational grazing system

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of

were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full

production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick

alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauai region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part 1 of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part 1*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain

the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean

water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing

system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were

Marisa Hurley
May 26, 2016
Page 13 of 13

intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: EIS for Hawaii Dairy Farms

I am greatly concerned about the potential affects of the proposed Hawaii Dairy Farms project planned for the Po'ipu / Maha'ulepu area. I feel that there are many issues specific to this situation which need to be carefully examined, as the project could create irreparable damage for the island of Kauai, environmentally, financially, and culturally.

I am a resident of Kauai, and have been working at the ANARA spa at the Grand Hyatt for 15 years, in the immediate vicinity of the proposed project I ask that the study be designed to address all of the following issues.

- It is crucial that the EIS be conducted in an honest and in depth manner. It therefore should be done by an independent organization.
Since Group 70 International has already been working with the HDF group, it is possible that they would be biased in their favor. It has been said, and rightly so, that it is possible to set up a study to prove what you want it to prove. Thus it is important that it not be set up with a pre-determined bias. Performing the study should be done by some organization not already connected to HDF.

- In the overall plan for the county of Kauai, it has long been designated that Po'ipu is the primary tourist destination area. People arrive here from all over the world to experience our environment of sunshine, clean air, beautiful beaches, and swimmable ocean. This area currently provides an abundance of hotels, condos, beaches, restaurants, and shopping. They will not continue to come here if their experience is one of the stench of cattle, manure, insecticides, or pesticides, or the pestering presence of flies, or an ocean that is polluted by run-off of chemicals, urine, and manure. They will not want to be driving behind cattle trucks transporting a load of cattle to various temporary pastures.

Kauai is a tourist dependent economy. The number of people employed by all of the tourist dependent businesses in the Koloa-Poipu area far outweighs the number of people who would be employed by HDF. There are thousands of people dependent for their living on maintaining a clean, healthy, tourist-attracting environment. It is not right to endanger all of these for the profit of a single new business wanting to come in. The EIS must safeguard this community.

Careful consideration should be given to finding a more suitable location for such a project than this one which is close and upwind from our major tourist area, and extremely close to sea level and shoreline.

- Kauai is fortunate to have one of the most beautiful and unique natural environments on the planet. It is a fragile ecosystem, so easily damaged. Any and all who are privileged to live here should hold it among their highest priorities to be the caretakers of this place, maintaining its health and protecting it. In this situation we are counting on those doing the EIS to assist us in preventing environmental damage, because once done, such damage is difficult, costly, and often impossible to reverse. I have read some of the other letters being sent regarding this issue, so I know that the particular details which need to be addressed are well documented. What I want to stress is that those doing the EIS must take seriously the potential impact this project could have on our precious Kauai.

-There also seems to be contradictory information being given about regarding the supposed benefits this project would bring. There is reference to supplying Kauai's families with a local source of milk. Yet elsewhere I have heard that HDF plans to sell most of the milk in the Far East. In some places they speak of grass-fed cows, yet elsewhere I have heard that they plan to use GMO corn to supplement the diet. So if there is any milk made available to Kauai, it will be contaminated with GMOs. If the current study aims to weigh the benefits and detrimental effects, these facts need to be checked out to see what the real situation is.

I surely hope that all of these matters will be strongly considered in designing this study. Thank you for your consideration.

In the Kōba-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kinoiki Road between Kōba and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasech Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3

construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of

soils in the adjacent Kōloa-Po'ipū region is on the order of 201 - 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kāihāeo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hatupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore

recreation waters at the terminus of Waipili Ditch, or of surface waters in the Māhā'ulepū Surface Water-Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waipili Ditch Sanitary Survey, Kaula, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to

increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaula I community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the

background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

Subject: Hawaii Dairy Farm on Kauai

Aloha to All,

We live in a condo in Poipu six months of the year and spend our other six months in Washington state. We both grew up around dairy farms and remember the cow manure jokes and flies that grow in it. There is no way that we know of that will contain the cow manure smell from spreading out into the areas around Poipu.

The farm needs to be in another area of Kauai and not the tourist destination of Poipu and the beautiful pristine area of Mahaulepu.

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4)2-9-003:001 portion and 006 portion
(4)2-9-001:001 portion

Dear Larry and Karen Jerdal:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in BIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could

Larry and Karen Jerdal
May 26, 2016
Page 2 of 7

inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila masoniphila*, the only Kaua'i species of native Hawaiian fly listed as endangered or threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhi'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kīnoiki Road between Kōloa and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for

six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical

value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural

District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural,

cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

Subj: Runoff to Ocean

Dear Ms. McIntyre,
Please excuse my intrusion in your time. In my "go far it" review of the new pending HDF purchase of Clover Leaf Dairy on the Big Island, I read quotes by the present owner-Ed Boteilho "Our land runs right down to the Pacific Ocean," said Ed Boteilo the farm's operator. "On a clear day, you can see some of the other islands. During the winter we often see whales swimming by." (a photo was submitted) **That admission ("Our land runs right down to the Pacific Ocean,") underpins the worst environmental disaster New Zealand has faced in modern history. Under the "prevent language" of 344-1, in what manner does one alert/involve DOH to this high potential? Does DOH have steam readings of the Kahalo Ditch or at the ocean as the run off leaves the Clover Leaf dairy? Who would I talk to?**
Thank You for your time.

Sincerely,
Ron

Comments, Concerns & Questions

Dear Mr Overton,
I have attached the full listing of questions, comments, concerns and questions I have organized re: the EIS of Hawaii Dairy Farms concept. I will also send by mail a hard copy. The other incomplete series sent to you by section are incomplete and should be deleted.
Please acknowledge by email a receipt of the attached 57 page document.
Thank You,
Ron

My questions begin with a concern. As Group 70 authored the HDF proposal, why would they not, as a matter befitting objectivity, discontinue quoting questionable written statements in writing as demonstrated in the text of the EIS preparation? Composition bias is evident and confirmed by their outline. The expectation of objective fact finding is lessened by their active participation. You should never rule on what you also actively participated in creating, nor place yourself in a position of validating your own veracity or competence. To be actively involved in the EIS deliberations only exacerbates this concern and creates unnecessary suspicion. **Group 70 should recuse themselves from determining any factual truths considered in this EIS study. Why do they not?**

I began Dec 23 /2013 looking at the HDF concept while reviewing Kauai as a place to retire. After my 16 Jan 2014 Guest Opinion was published in the TGI, the HDF spokesperson with others in the room with her, called me. One of her questions to me was to paraphrase: "Why was I so concerned when I didn't even live there?" My answer was pointed. The gist of my response was: "Not there or anywhere should such a mistake be made." I think I referenced the Sistine Chapel as an example. I have lived and owned property in Kauai. I have family there. For many reasons it is my favorite place on earth. Careful regard should be given to such places wherever they might be.

My personal concerns/questions are multiple and have been discussed with experts in the field of agronomy, dairy, hydrology, atmospheric/weather, seismic activity, irrigation systems, statistics, and many others. A general over view and concern is the "One size fits all" mentality demonstrated in proposal areas requiring far more specificity and accuracy. The proposal as it now stands is a collective failure of due diligence. It appears more typical of an infomercial presentation attempting to promote a point of view, but void of sensible or reasonable conclusions. It is at best, conclusory allegations that have no support; void of the serious, deliberate analysis of data HDF should have submitted. It is riddled with inconsistencies both confusing and contradictory summations denied

RJ 2

by its own data. It is a "shoot oneself in the foot" performance, with HDFs own data conflicting more with its concept than supporting it. **By what standard was the HDF proposal written? By what standard was it judged?** Their method of analytics within a few pages becomes upside assertions, hardware boiler plate specs, promises and little objective support of stated/expected outcomes. **Can the EIS review process give a definitive summation of "suitability" of this proposal to present necessary information and true data based conclusions?**

Is need or necessity for this proposed commercial project within the scope of this EIS? If it is then a value contrast with any other use construct for this land is warranted. The underlying premise advanced with all manner of endearing phrases by HDF is that milk and thus this dairy is a necessity, a marker of a sustainability index of Hawaii's well being. It is not. Milk is an option not a necessity. The National Institutes of Health reports that around 65 percent of the human population has difficulty digesting cow milk. The dependency on cow milk much like the human appendix is no longer a valid argument. Its need, which in my beginning years of the 1930s depression may have been warranted, has been replaced by far better nutritional options of equal cost or lower if Ulepono Initiative wanted to truly meet Hawaii's basic needs, they would best served Hawaii if staying with their stated goal of solar power.

HDF EIS PN lists proposed action: Establish and operate the first grass-fed dairy in Hawaii, utilizing a sustainable, pasture based rotational grazing system. Produce fresh, locally available nutritious milk for Hawaii families

No part of that "proposed action" is factually true. From failure to qualify as a **"grass fed dairy"** by definition of grass fed dairy to **locally available**, it is pure hype and contains nothing of substance. Meadow Gold owns the milk when it comes on island in Oahu and will mix it with other state side milk sources during the pasteurization process. **Sustainability** can be a deceptive generalization, often a word wrapped around "an essential

RJ 3

needed by " or " for the long term good of the people." Often however it is a filmy cover of a "for profit" motive only,

By HDFs own indication "qualify for international sales" the intended sales target is obvious and not **just for Hawaii families**. Finally why would any of Meadow Gold milk be other than **nutritious** whether for **Hawaii families** or for any one else? It is a PR green washing of new proportion. Hawaii deserves more than a spin doctor, emotional appeal. **Actually the real concern voiced by Kauai residents is "price of this particular product;" on that need, HDF has not yielded one penny.**

The basic information needed for any purchase or lease of land required to be a primary food source for cattle is knowing the quality of the soil, its type, its water holding capacity, the water requirements of the crop being considered, and many other related soil and water essentials. Will the EIS explain their misrepresentations? Why, after "five years of study" was this basic information advanced in error when submitting the first proposal?

HDF began the permitting process by submitting their application/proposal for approval by informing the West Kauai Soil and Water Conservation District that "the soil was free draining". They were believed at face value and approved, yet that basic assertion was both misleading and untrue. After being corrected, HDF continued to base conclusions as if it remained the same "free draining soil." One would believe that an NRCS review would have, at minimum, pointed out the many deficits of HDF's original proposal. Although NRCS officials made clear they did not "approve" the proposal, HDF continued to quote "approved" as support for their actions. NRCS, in my own opinion, failed their advisory/investigative capacity in this particular matter. **Should this deceptive beginning be an EIS concern?**

A clear indication of HDF awareness and the certainty of the farm flooding is given on pp; 73 last submitted proposal (Quote) "The dominant soils on the lower farm are Ka'ena Clay, Kalapa Silty Clay and Kalihi Clay (actually there are Ka'ena Clay and Kalihi Clay type soil extending much farther through the farm in all directions-writer notation) which are prone to compaction and all are characterized by poor draining. "However less than two days after heavy rain, with rapid removal of the surface water during and after a significant rain event, they are observed as being dry

RJ 4

enough to graze even without a Kikuyu thatch." Just that admission should close the door on this site selection. It is self- confronting and damming. Keep in mind there are 352 Acres of Ka'ene Clay and Kalihi Clay poorly draining type soil and that type soil extends much farther into this farm site and in all directions. **Will the EIS review evaluate the meaning and end result of applying this data?**

"Poor draining-"rapid removal of surface water" To where? With that admission, what other indication is needed to verify that draining manure laced soil to the streams is going to happen? If there is another definition to zero discharge what is it? If there is truth in the statement regarding soil type quoted above, on what basis would this farm site qualify as "suitable soils?" (see Group 70 EIS Preparation Notice pp.2-1) The words "promote efforts which will prevent or eliminate damage to the environment and biosphere---(Chapter 344-1) are clear. **What reasons, methods, or new knowledge will in reality support that the dairy project can do other than create serious damage? "Prevent" not wait until?**

The land total of the soils listed on pp3-1 of the HDF EIS Preparation Notice as Kalihi and Ka'ena soils is 352 acres. These soils have a Ksat level from 0.00 (no capacity intake) to 0.20.(1 fifth of an inch per hour)(pp 12 HDF proposal) A University of Nebraska dairy expert (name given by request) indicated that those soils can run off almost instantaneously," yet on pp 42 is the explanation that a 0.39 inch of water (as the pivots are rotating) is put down on the 352 acres of that soil type. The spray is by applicators dropping that amount as they continuously move- not a same spot application over longer time duration as does rainfall. **Will the EIS evaluate how it is possible that such application; approximately twice higher than the highest absorbent capacity of the soil, and on top of manure already deposited on the field, does not create a run off of a mixture of water and manure to on field drainage systems and on to the ocean? Drainage systems are not holding ponds. (see code 633 Waste Utilization page 2 of 3) "When liquid wastes are applied the application rate shall not exceed the infiltration rate of the soil and the amount of waste applied shall not exceed the moisture holding capacity of the soil profile at time of application. This is basic to every rate of application of liquid waste or water. Will the EIS review tell us what in the proposal, other than promises, display that this basic is**

RJ 5

understood. How was the limiting factor - holding capacity of the soil in the area recognized? What is unclear to HDF about this regulation? The ignoring of this understanding is replete throughout the entire proposal. Other than an overriding intention, what other reason can explain the ignoring of such clear, necessary, appropriate agricultural regulation? It is a basic agriculture standard.

Page 40 HDF proposal indicates a pivot rotation schedule of 40 hours each pivot. Poipu (next to the dairy) has a 16.2 mile an hour average yearly wind with gusts to 40-50 miles or higher an hour. Farther north toward the mountains it is higher. Sophisticated VRI irrigation systems can interpret weather conditions, but sudden, random gusts of higher winds first have to occur before shut down is activated. **All interactions have a time interval. Multiple ditches and streams traverse the areas and run off to the beach. Under these conditions, can an overspray wind drift transfer to the water ways occur? Why not?**

Irrigation experts point out that VRI equipment with so many more interactive components are prone to problems, and that the spray residue left on the pivot equipment may drop off when moving across ditches and streams. Is there a possibility that this contamination /pollution of the waterways will occur?
80 hours is required to irrigate not counting the time required for effluent spraying. Given the average yearly 16.2 wind factor, and the nutrient requirements determining the pivot use schedule, if held to a standard of no overspray/wind drift can HDF demonstrate how their irrigation scheduling requirements can be reasonably meet?
Does the failure of proper effluent and irrigation application scheduling effect all other nutrient variables?

On pp 39 of the HDF proposal is Table 12- is a listing of required irrigation days per month. No one should use averages in this type calculation nor apply any application on the basis of average. If the nutrient needs are spoken of as averages that too is wrong. HDF does however, indicate "significant rainfall in these months is probable and could cause the soil to exceed capacity from rainfall alone" (pp39). HDF does not show precise area soil Ksat data. **The Ksat data is given as a range. Its capacity to take in moisture could well be 0.00 (none) and not the highest rate of 0.20. How then can the same rapid rate pivot irrigation concept of**

RJ 6

0.24 have any merit in reality? Isn't runoff or flooding the outcome of "exceeds capacity of rainfall alone?"

Given the information of the last question and the conceding of a 10.4 rain event by HDF, where would the millions of gallon (27,154 gallon per acre per inch of rain per hour) run off to from the other 576 acre(not counting that in the effluent ponds) when the manure covered fields receive this same rainfall amount? A 10.4 inch rain event on saturated soil will send 162,000,000 (162 million)gallon of manure laden rainfall on a downhill course 0.7 miles to the ocean. That event was described by a rancher as "water higher than the 4 foot fence posts."

A 24 hour 100 year review of storm participation was offered as proof of compliance by an HDF spokesperson 23 January 2015 (Quote Amy Hennessey Jan21/15 TGI) "Our farm's effluent ponds are designed beyond the requires size to accommodate a 24 hour 100 year rain event." HDF uses the figure of 10.4 inches in a 24 hour time frame. That data is not remotely true.

National Oceanic and Atmospheric Administration data from 1950 till 2000 (50 years) will point out how much defining data was ignored or left out by HDF. Specific to Kauai: there was Hurricane Hiki in 1950 with 52 inches falling in 4 days, Nina in 1957 with 20 inches of rainfall in 14 hours, Dot in 1959 with the eye directly over Kauai, Iwa in 1982 with all gauges down-listed as Heavy rain, Iniki In 1992 all gauges down-listed as Heavy rain. If anything was left standing including dairy cows, these Hurricanes would have filled the ponds and quickly brought them to an overflowing, runoff stage.

Quote: "It is commonly believed from recent history that Kauai lays in a more vulnerable position than the other islands. However, in his recent analysis of Hawaiian hurricanes, Dr. Tom Schroeder of the University of Hawaii, Meteorology Department, concludes that every island has been affected by hurricanes and that no island is without risk." (NOAA report)

The unpredictable direction of hurricanes and tropical storms is a meteorologist's nightmare. Indicated in a 2002 NOAA document Atlas of Natural Hazards in the Hawaiian Coastal Zone is data showing that in just 43 years- (not 100 years) between 1950 and 1993 there were 25 Hurricanes that hit the islands, and an additional 33 Tropical Storms rain events

RJ 7

occurred statewide. In areas of known seismic activity, construction building standards, integrating that factor, are mandatory. So too are DOH standards for properly sized effluent ponds. Given "no island is not without risk" what support if any, can HDF give for not constructing effluent ponds based on actual rainfall data? What are the new dimensions of the ponds and the capacity? Were they designed on a 2000 dairy cow basis. Page 47 indicates "The pond is oversized to allow for Phase two effluent volume requirements yet it only displays "Phase 1 Minimum Volume gallons .Roughly speaking 2000 cows will fill the pond 3 time quicker than 700 cows. On page 53 one reads (Quote)" even twice this amount at 0.25 in won't be excessive if the soil moisture levels allow" That statement leads one to believe that HDF hasn't yet considered the now known and dominant major soil type (poorly draining) and ksat indication (0.00 to 0.20 in) that they are truly working with? Will the EIS review this area?

On 15 February 2015 Kayle Datta (senior partner Ulepono Initiative) in a TGI Opinion wrote "To be clear, there has been no storm event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Mahaulepu Valley" Three main concerns regarding this assertion need answering by the EIS review. One is the certainty that only at one time will the effluent ponds be totally empty . The milking parlor is in continuous use facility. The wash down and manure from the dairy cow, calving pens etc are flowing to the ponds on a 24 hour a day cycle. **What is the square footage of all areas that run to the effluent holding ponds? What is the total amount of water, manure and urine, general cleaning procedures, including wash down of each dairy cow and waste from the calving sheds etc. that will run into the effluent ponds per day?** On page 26 and 43 are listings of "gpd" (gallons per day) usage of water. On page 43 we see an indication of "2640 gpd Machine wash." In reviewing "gpd" it is difficult to find any wash down system that uses less than 6.8 gpd per dairy cow. HDF will wash down the dairy cow 2 times each day with a total of 3.7 gallon per day. **If more than that amount is required a 2000 cow wash down would place a significant higher**

RJ 8

amount of waste water in the ponds. Will the EIS be specific enough to analyze these possible variations? What are the new sizes of the ponds? Are they sized for 2000 dairy cows? If the total sq. ft area is larger than 16000 sq. feet (approx. 1 third acre) can one assume that a 1 inch rain event would by itself add approx.9000 gallon to the ponds? If that is correct how much more is added by the 1 inch rainfall runoff from all other milk parlor areas that run off to the ponds? The second concern is the narrow weather bandwidth of" rainfall in Mahaulepu valley" as a determinant of pond size. That data needs EIS review not just of an individual rain gauge, often not working, but rainfall from a much wider area (Lihue Airport for example)). NOAA weather records etc.) Third- it is not the effluent ponds that will do the most damage. It is the total rainfall amount of sustained storm events over successive days and which are significantly beyond Ksat intake ability that determines the outcome of these interrelationships. . **Wouldn't rainfall numbers charted against Ksat capacity numbers reveal whether/when runoff will begin?** It becomes a pollution runoff certainty when a rain event occurs and the high AU ratio to acre pod grazing method (300 to a pod) has left such a high amount of manure to be washed away from fully saturated soil. By the stocking rate(300 dairy cows per pod) the 3.2 to 4.2 acres pods become uncontained zones for the mixing of manure and rainwater.2,000 cows grazing on approximately 24 per day (83 cows per acre), will result in at least 200,000 lbs. of manure and 16,000 gallons of urine left daily on the clay soils found on the farm site On a "poorly draining" soil pod with a multi-day series of rainfall or a one day rainfall above 0.20 inch per hour, that combination of factors will result in runoff. Residents familiar with the area tells of "rapid rate rainfall that "started brown water run off all most immediately from its beginning." Protective barriers/berms are mandated to protect from fecal runoff from roadway ,raceways, runways and walkways. **What protects the steams from the runoff from pods?** What other explanations/outcomes are there? When used as a cane field it, as a matter of course, drained to the ocean. As the pods would now be covered in a high volume of manure that result is not allowed to happen . There are 26 single days in the last 25 years which

RJ 9

exceed the amount of rain that created significant flooding from run off of the HDF proposed dairy farm area. That 2 day amount of Feb 16 and 17th 2014 was 3.20 inches and flooding was noted. **Will the EIS confirm/ answer these concerns?**

Conspicuous by its presences, and also by its disregard by HDF planning, is a Taro Farm in the lower left hand quadrant of the property. That private property requires flood irrigation, yet abuts a sludge containment area containing 82 acres and block F of 54 acres, which is described on pp73 "are perceived as heavy, flood frequently and difficult to crop. **No indication of protection or concern for the Taro Farm is written and runoff, over spray or intermingling of its water with effluent mixed water is not considered. Why not? What should be done to protect the Taro farm from this intrusion? By the same token what keeps the taro farm from spilling into the HDF farm site, mixing with the 82 acre M and S area and then draining directly to the ocean?**

Many states have Odor minimization plans Counties, townships etc. are growing rapidly in number as they put restriction on this form of pollution. The recognition of the profound effect foul odor can have on the physical health of residents, and the debilitating outcome it will create on the economic climate of the community is becoming more based in scientific certainty. In Kauai 1000 jobs at minimum are on the line the first time a foul odor drifts to 1.7 miles from the dairy farm to the front door of the Hyatt and other nearby resorts. That downside information will travel around the tourist industry truly at the speed of light. Residential property values will significantly decrease as well as a significant tax income deficit will hit Kauai. **The health issues are numerous and a plan must demonstrate consideration for those about them. An EIS review should reveal if there was any evidence within the HDF proposal of this consideration. That review should assure and describe in detail on what basis these outcome will not occur. A row of Norfolk Island pine won't do it** The assurance given by HDF i.e. the cow will fart less, and nutrient supplements will make it smell less doesn't cut it so to speak.

RJ 10

My daughter and her family now live in Kauai. They, as I know, what Chino CA and now Tulare Co. in CA, smell like England on a cross wind day can smell France's farm area. A farm odor of the nature of that which will be created is not compatible with the existing environment. Anaerobic digesters (which they did not select) can cut the odor down. Digester would help to minimize greenhouse gases, but nothing can stop it entirely. Even if digesters were used for the manure washing to the effluent ponds, there still remains the high tonnage of manure dropped on the paddocks each day. That element will ripen in the sun or rain and the wind speed and direction, ambient air temperature, stability class, mixing height, and precipitation and pressure, will decide "that odor is headed downtown Koloa and Poipu. HDF's manager was a CAFO manager in Vado New Mexico in 2006. That "Dairy Alley" between Las Cruces and El Paso is known and written about by a national newspaper and featured by NPR. It is infamous for its pollution and smell and well the HDF manager is aware of it. The sludge dumpage on 82 acres is environmentally intrusive and unnecessary. It demonstrates corporately insensitivity to others around them. This placement of the sludge area closest to others(1.5 to 1-7 miles) outside the lower Mahaulepu Road fence is truly an "in your face" nose thumping at Poipu. Koloa and the Lawai valley.

A odor minimization plan appears as an HDF postscript. HDF has treated that critical area with one line "All material will be handled in a manner to minimize the generation of particulate matter, odors and greenhouse gases."(HDF pp.85 first proposal) The same lonesome line is on page 75 of the 3rd proposal. It is not mentioned in the redacted proposal. That's it? Just the word or suggestion of odor mentioned once in a 100 page industrial sized dairy proposal? An apparent fill in the blanks or after thought? "Odor Minimization" no big deal-not even a mention in the proposal table of contents? When first approaching a dairy you might first spot the silos. No later than 2nd you smell the dairy. In " Understanding Concentrated Animal Feeding Operations and their Impact on Communities (Hribar and Schultz National Association of Local Boards of Health 2010) one finds a more serious understanding and summation.(Quote) "One of the most common complaints associated with CAFOs are the odors

RJ 11

produced. The odors that CAFOs emit are a complex mixture of ammonia, hydrogen sulfide, and carbon dioxide, as well as volatile and semi-volatile organic compounds (Heederik et al., 2007). These odors are worse than smells formerly associated with smaller livestock farms. The anaerobic reaction that occurs when manure is stored in pits or lagoons for long amounts of time is the primary cause of the smells. Odors from waste are carried away from farm areas on dust and other air particles. Depending on factors like weather conditions and farming techniques, CAFO odors can be smelled from as much as 5 or 6 miles away, although 3 miles is a more common distance. (Understanding Concentrated Animal Feeding Operations-State Environmental Resource Center, 2004)

To the writer the obvious absence of concern for this area is telling, shaming, and inexplicable. It flaws the due diligence aspect of proposal preparation. It is a glaring disregard of basics and its lack requires explanation in the EIS review.. Why or how can this factor be seen as insignificant by anyone of any level of agricultural knowledge? What tangible data support can HDF give that demonstrates no odor drift? What odor carry distance data have HDF developed beyond the HDF spokesman -while in New Zealand- not being unable to smell the effluent beyond 20 feet? What is the spectrum of health risks and environmental degradation? How are those elements clearly mitigated? What is the plan? As a small example why, if only for Koloa and Poipu's well being, is the sludge area located on lower Mahalepu Road, nearest (approximately 1.5 to 1.7 miles) to Koloa and Poipu and not located to the rear by the effluent ponds?

All of the land where the Hyatt and other resorts are located were once zoned for agriculture use. **"How can this proposed dairy project location be considered compatible or justified. What is meant by "compatible usage"?** Sec 8 1.5, *Kauai County Code, 1987, as amended* defines compatible usage as follows: "Compatible Use" means a use that, because of its manner of operation and characteristics, is or **would be in harmony with uses on abutting properties in the same zoning district.** In judging compatibility the following shall be considered: intensity of

RJ 12

occupancy as measured by dwelling units per acre, pedestrian or vehicular traffic generated, volume of goods handled, **and other factors such as, but not limited to:** vibration noise level, smoke, odor or dust produced or light or radiation emitted. (Sec. 8-1.5, *Kauai County Code, 1987, as amended*) **What is meant by "and other factors such as but not limited to" in the above cited Kauai County code.? What does "odor" mean as mentioned in that Kauai County code?** When a project at best puts up as collateral a promise that it may result in 15 jobs and a product shipped off island to be mixed with stateside milk and also clearly states it won't be lower priced; **what indices justifies the risk of harm to benefit ratio?**

RJ 13

HDF EIS PN Kauai -Ronald John

2nd Series of comments- questions and concerns

The inability of most of the soil to percolate, the limited capacity of the ponds to hold an actual measure of what rainfall could bring, and the sustained and periodic rain events which last for days or weeks, (much as the 40 plus inches Easter flood of 2006) will create an uncontrolled release of polluted matter. In February HDF was sent pictures of the ""Easter" flood damage.. Seeing the clear, evident flood damage and knowing that other rain events have been left out of HDF considerations; for example In Dec 15 to-16 2008 a totaled of 11.11 inches fell at Mahaulepu, **why and for what reason is such information not been given due consideration by HDF? What specific reasons or improvements can HDF indicate that would explain why no pollution will leave the property? It isn't just about an effluent from the effluent ponds.** Every rancher that has used this property has seen the entire area flooding and often. Just last year the road below it was flooded. It is not an uncommon occurrence.

Amy Hennessey spokesperson of HDF wrote. "Water quality management is an important part of the plans for the dairy. We will be implementing a water quality-monitoring plan to help the farm be protective of the environment." A water quality monitoring plan tells you what is or has happened. With rapid run off release that time is often too late. What HDF doesn't seem to understand is the difference in what they say they will do, and how. **HDF does not have a "how to do it" plan to handle pollution run off nor how to prevent it. They speak of it as a given or an accident, Why. Monitoring stations will tell you of it, but who needs a device to tell you its flooding? Then what? Call it an**

RJ 14

accident? (Certainties are not accidents) Move the cows? The dairy cows are either trying to stand up on slick water covered, non- absorbent clay soil or perhaps learning how to swim. **This area must be covered in the EIS evaluation process.**

HDF has presented a concept that preceding a rain event, overflow possibility they will empty the effluent ponds out on the fields (see page 54 HDF Quote) "if warranted due to potential impact from an approaching storm event the settling pond could also be pumped empty with in an additional 40 hours") This is an intentional transfer of waste when under threat of a weather event. EPA does not approve/condone that action (see Sec 633 Page 2 of 3 under Additional Criteria to protect water Quality). "Agricultural waste shall not be land applied on soils that are frequently flooded, as defined by National Cooperative Soil Survey during the period when flooding is expected." The manure covered fields would already be facing an overflowing of a mixture of manure and rain and such an additional dumping of effluent will add to that overflow...

The basic expectation is zero discharge. The first gust of wind on a windy evening at Mahaulepu, and the tall irrigation pivots and gun arrangement will leave pollution in the water ways of Mahaulepu. According to HDF there are 14 ditches traversing the property. No reputable irrigation expert or VRI representative will tell you that these devices are free of a level of spray scatter, mist or wind drift when operating, nor will they tell you that the system is a 100 percent error free. It is generally recommended that spray application of wastewater should be done under low wind (less than 5 mph) conditions and after mid-morning, preferably in bright sunshine **What VRI error rates were known by HDF? Given the 16.2 average**

RJ 15

wind speed at Poipu, in what manner can HDF spray effluent when needed, and make any assurance that polluted effluent doesn't reach the streams? What regulations have HDF adopted re: spray application and wind force?

Quote HDF spokesperson: "Most of our animals live, long, happy and milky lives."—Compared to the human species, the dairy cow is the princess and prima donna of the bovine world. She is far more sensitive and fragile than her cousin the range cow. To some she is a liquid white gold machine; an ATM so to speak. Unlike wild animals, the dairy cow cannot leave her pasture to seek protection under harsh conditions. You need to provide it for her. She will not want to be inside all of the time. However, she will need a shelter option when the weather gets nasty for prolong periods of time, need to escape fly swarms, or simply to rest.

Few animals are comfortable when eating or laying in close proximity of fresh feces. This condition would be especially true if the dairy environment is configured as HDF has designed it. When the tightly grouped mob of 100 to 300 dairy cows on one small 3-4 acre pod begins to download tons of fresh manure at the same time, and in the same area where they are grazing, when they have been exposed to a rain event for consecutive days and standing in mud till foot rot begins, when it is unseasonably hot for days, the irrigated effluent is ripe and flies are on them from all angles **what then is the remedy? Why is HDF not building a shelter for the dairy cows?** If for no other reason, income studies point out the significant added income when you have a "satisfied" dairy cow. Other groups including some civilized countries see this as humane. Be it your heart or your wallet she needs shelter. **Why is HDF ignoring this**

RJ 16

need? What shelter of any sort will be provided?? When more serious storm events occur where do the cows go when flooding occurs?

HDF has not shown an active concern for a shelterbelt location. Why not, and if they have one, how workable is it?

On Page 73 8.4.3 the Mahaulepu soils, particularly in the south central portion of the farm (Block F, figure 23) are perceived as "heavy, flood frequently, and difficult to crop." There are like soils with the same Ksat rating. A statement that "they are "observed" as bring dry enough to graze even without a Kikuyu thatch" is below and begs any acceptable standard of verification. "Seems good -looks good" doesn't cut it so to speak. This is a critical factor .Where is the data? What does it say?

Why did HDF state "the dominant soil types on the "lower farm" when actually these soils extend from lower Mahaulepu Rd 2/3rd or more, through the middle of the entire property, and poorly draining soil is the dominate soil type not just of the "lower farm" but of 352 acres of the property being used for grazing purposes? How does HDF reconcile the separate and different irrigation concept for Block F and not the other 300 acres composed of the same soil type (poorly draining)? Shouldn't the soil type define the irrigation method? These soils are group D soils (see: Department of Agriculture Natural Resources Conservation Service Part 630 Hydrology National Engineering Handbook Soils in this group have high runoff potential. " Group D. Soils having a very slow infiltration rate {high runoff potential} when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a clay pan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission."

With soil type differences, different irrigation methods and nutrient limitations, has HDF successfully irrigated the kikuyu, and does proof of such successful trials exist? What is that proof? What trial data, date, and field location demonstrates the 18 day recovery

RJ 17

rate claimed and used to support the rotation of paddock at an 18 day level? What trial data of tests ran on different soil types at Mahaulepu supports that conclusion? Does the kikuyu yield, if any, match their indicated nutrient needs? How many acres of Kikuyu have demonstrated/met a 20 ton "kikuyu yield goal?" (page 57) What is the nutrient differences in Kikuyu and a mixture if Kikuyu-Guinea grass (page2-2 HDF Els PN)

On page 73 a mention of "drainage system" is noted. Keep in mind that any drainage/runoff of a grazing area is of an area covered by recently fresh manure and or effluent, the lower farm area is generally at 61 feet elevation, the effluent ponds are at an elevation significantly higher, the adjoining streams and drainage ditches run to the ocean. **With full understanding of what "zero discharge means" how does HDF explain why stream water pollution won't occur?**

Kauai needs development that adds economic security and stability. This HDF type intrusion on the south shore of the "Garden Island" is without precedent. The negative economic impacts possibilities stand out clearly in the light of studies from other CAFO areas. Never before in the world has any one attempted to locate a CAFO this close to an upscale residential, hospitality oriented, internationally known, ecological, archeological significant, and spiritual environment; one so highly rated that national park status is pending..

CAFO's can devastate the environment and human health. The presence of a facility like a CAFO reduces overall tax revenues. Assessed evaluations of land and houses nearest this industrial dairy will consistently

RJ 18

decreased by 20 to sixty percent in recognition of the loss of value that accompanies the odors, flies and other forms of pollution from the CAFO. Studies show that (Quote) "resulting losses in property rates are impossible to be made up from the new taxes generated by the CAFO for two reasons: first, a CAFO is specifically structured to minimize the amount of local taxes it pays and second, a CAFO is capable of polluting a substantial area around its perimeter and this area is likely to have an assessed value that far exceeds that of the CAFO."

The Hyatt employs a thousand people. This particular CAFO, by its own admission, offers 10 to 15 jobs, which HDF indicates in their proposal, may not likely be filled by locals. That point is reinforced by reviewing HDF hiring practices so far. The present HDF Manager is a former CAFO manager from Vado New Mexico; a dairy area noted as one of the most polluted in the state and one written about nationally. So far work has been mainly by New Zealand crews under the direction of an onsite general contractor from the east coast of the USA. If the measure of this concept is jobs created and dollars left on island to circulate among other vendors on the island, then what HDF brings economically to Kauai, can be replaced by a local, quarter acre sized, locally staffed "Dairy Queen Drive In" with no downside .. **Has that potential downside of this experimental dairy been examined? Under the principle "First do no harm" what are the factual assurance of "no harm"?**

Public Nuisance laws are being tested by this HDF dairy intrusion. The law regarding public nuisance is more and more focusing on industrial dairy intrusions. As their pollution affects are quantified there is a widening in definition. Legal interpretations often see this type of incursion as

RJ 19

unlawful, "an unreasonable interference with a right common to the general public, or an activity considered unreasonable as the gravity of the harm to the public right outweighs the utility (benefit) of the activity. **What case law is used by HDF to support their dairy incursion on already existing neighbors?**

HDF continues to reference water conduits other than the effluent ponds. On page 5 of their last know proposal, they speak of "water wells, reservoirs, irrigation ditches, drainage ways and culverts" On page 49 they speak of "existing drainage way." As previously noted, on page 73 is a mention of "drainage system." In addition 2 fixed cement water troughs per paddock would make 236 fixed water receptacles; all inside the effluent spray zones and within over spray/mist distance. It is understood why effluent ponds are required especially for close containment CAFOs, but in this new model, all the property not occupied with or by the milk parlor (570 plus acres) is a receptacle (a tilted to the South East, giant saucer if you will) for a manure and urine loading not consider nor regulated in Hawaii before. The Maximum load of cattle grazed at the HDF farm site from 1995 till now has been approximately . 300 range cattle, yet the streams running through the farm site and on to the ocean are polluted to an extreme with that load of cattle. (see Surfrider and DOH data). **What created this pollution? Could it have been from the cattle being pastured there?**

One fact must be emphasized. **1 inch of rain per hour drops 27,154 gallon of rain on each acre. One local rancher indicated that "heavy rains in that area have started run off almost immediately". Obviously then-in this poorly draining soil- a "rapid rate of rain" fall will also create flooding conditions.** HDF clearly confirms the ranchers statement of

RJ 20

rapid rate of rain fall runoff (see page 73 Quote). **"With rapid removal of the "surface" water during and after a significant rain event". --"rapid removal" of "surface water" "during"-- What other assumptions/interpretations can be made from their open admission?**

. A serious rain event could cause a certain overflow of the effluent ponds, but an unmitigated disaster would be occurring as 8 million gallon of manure laden water per inch of rain per hour, from the rest of the 574 acres remaining , will begin a down slope runoff to the ocean just 7 tenths of a mile away. No longer, as in cane or taro production, is it supposedly just a run off of muddy water. With 3 inches of rainfall on just the 352 acres of poorly draining clay soil you would have 28 million gallon of mixed manure and rain flowing off property. That figure is 17 million gallon more than the Exxon Valdez oil spill. (11 million gallon) spilling on a world renown reef and covering a 10,000 year old "Cave full of artifacts and threatened species" that simply can't be replaced at any price...**When using the 10.4 rainfall figure given by HDF and applied to 574 acre shallow dish catch basin as the farm property can be described. That full run off figure becomes a 168 million gallon run off from property. One rancher indicated that "water ran over the top of the farms four feet high fence posts. The EIS should consider the "prevent" wording of 344 State Environmental Policy. This data alone should factually support that this site is wrong and that the dairy belongs on a more suitable site. What information/data if any invalidates this high and statistically certain risk and of which HDF data confirms?**

I do not particularly "love" the dairy cow as the HDF spokesperson has indicated. HDF does (Quote Amy Hennessey "We love animals"-Jan

RJ 21

29/24 TGI.) but I do understand her (the dairy cow). Range cattle seem to move quicker than Dairy cows but the pace for both is slow. I have trailed cattle. I cannot conceive of a HDF workable concept that explains how to get a 300 cow mob up a raceway to the dairy parlor yard while 300 more need to leave that area and go back to the same pod they came from. I do not believe that the HDF paper concept will work under real life and varied conditions. At no time can you effectively have coming and going, intermingling mobs, cattle traffic. Such a stock traffic pattern would require clear fixed separation. It they must get one mob back to its pod before the next mob starts then the predicted time schedules are not close to real. If they use quadrant separation of the six daily required paddocks then the pivot irrigation concept is complicated at best...The outside perimeter distance of the paddock to the milking parlors appear to range between 200 yards on its west side just beyond the calving sheds to over one mile and a half south to Mahaulepu Road, It is, a mile to the northern tip and east edge of the farm. If a dairy cow is more than 900 yards from the dairy it will not work as indicated. Studies indicate the dairy cow pace at average is 1000 yards per hour. At this time there are range cows near the HDF property. Borrow one from the Mahaulepu road area and trail it up to the milk parlor area at normal pace. Keep in mind the dairy cow would be carrying an average of 110 pounds of full udder weight also, wait for reasonable intervals (as long as it would take to get her washed down, milked, fed and back to the original paddock). How did it go, or better where did the time go? The stated maximum build out of 2000 cows will result in 4000 milkings, 12 rotations, every 24 hours without interruption. **If one waits as described to get the dairy cow up and back before the next mob begin**

RJ 22

this rotation, how are the 12 mob rotations (to milk parlor and back) accomplished even under normal conditions? What data supports such practice?

The need for continual 24 hour full operation leads to the next concern. Very few dairies exist that brings so much varied power demands at such a constant high draw level. From electric fences to refrigeration, from automatic milking machines to roads, ramps, raceways lighting, paddock fencing, system pumps, such as those for the effluent ponds, and paddock watering trough systems; what happens when power is lost as it was 2 weeks ago (mid Jan 2015)? No separate backup power is mentioned in the HDF proposal nor could a backup generation system of normal size power up enough to handle the full electricity demand of this dairy concept. In a major storm event-- power out over days- what will be done to maintain the viability of a sensible dairy operation? Do plans exist showing an off line from main provider secondary power source? What is it? How does it work? If the solar paneled roof concept is conceived as adequate to meet an offline from main source line need, then that data must be demonstrated re: a full and complete storage/usage/ demand comparison. That comparison must be projected over the usual/common outages occurring in that area and for outage times reflecting major event disruptions. What data exists re: Photovoltaic solar Modules (solar panels): and high wind created loss of these panels by wind force? What is the possible wind load of that area of the farm?

RJ 23

3rd Series HDF EIS PN Kauai Ronald John

Comments concerns and Questions-Kauai

What follows is additional information re: the HDF partial review and claim of a 100 year review by their Spokesperson and used to support the size of the effluent ponds. It is an Example of content in a 2002 NOAA document: " 1950 Kauai: 52 in rain over 4 days, flooding."1957 11/30- Nina NNW, passed Kauai 92 8 21 35 Kauai: 20 in rain in 14 hrs, 12 homes damaged by \$1,056,000 -----(Chart 5)" (Atlas of Natural Hazards in the Hawaiian Coastal Zone
By Charles H. Fletcher III, Eric E. Grossman, Bruce M. Richmond, and Ann E. Gibbs Prepared in cooperation with University of Hawaii, State of Hawaii Office of Planning, and Natural Oceanic and Atmospheric Administration.

It is information too important to be ignored, left unfound or not used. It changes the parameters that safety and well-being requires. **Why has HDF failed to acknowledge in full all the weather events that would at minimum, significantly disrupt dairy production? Given the variability of weather patterns shouldn't all the full island weather conditions be taken into consideration. If not why not?**

If one analyzes just the Mahaulepu rain gauge data he will find 11 rain events that were 6 inches or more occurring in the last 25 years, if he reviews successive day rain events he will find 6 that were over 8 inches and which happened in the last 14 years. **If evaluated by approved objective evaluation standards, you would find that in each one of these 17 rain events (when applying only three known facts- soil type "poorly draining", 352 acre total, and Ksat level (0.00 0.10 or 0.20) Lowest ,average, or highest Ksat level shown-you will still have one result- flooding beyond the HDF property.**
. What evidence contradicts those findings?

On page 27 of the HDF proposal is a description of the 236 watering troughs HDF will use; "high enough for the animal to reach over and in but will discourage the animal from stepping in." A cow, at times, seems to become confused as to knowing which end they drink with. This has been observed as a good reason to not drink downstream from the herd. **Can**

RJ 24

this misinterpretation of which end should be next to the water trough happen in regards to the HDF water troughs?

Indicated is "refill the trough as the water is consumed." What happens to the water in the trough when the paddock is emptied and the water trough is full? "Does it then automatically drain (explain that mechanism) or sit full, partially full etc. and stagnate for the next 18 day rotation cycle? Can it be filled or emptied manually if the main power is lost or if some form of pollution is noticed in the trough? Even the best water troughs accumulate dust and other particles. Over multiple hot days it's not unusual to see a buildup of undesired elements. Who cleans the trough ?How and how often?
What set back footage figure from the troughs will be used to determined that overhead spray of effluent does not fall or be blown into the troughs? It is presumed the wheel tracks for the pivot system are set and not close to or encumbered by the fixed in place troughs? Are they?

On page 4-1 of the HDF EIS PN is the statement "identifies the region as important agriculture land for Kauai." It would appear that such terminology mainly represents the ability of the land to be use in flood irrigation type context i.e. a Cane or Taro field for example, or that the soil type was not considered in determining such IA designation. Grove Farms allowed a massive dumping of Class B solids by Aqua Engineers on land in close proximity to the HDF site. That is hardly an indication of "important agriculture land" consideration, and the meaning of such designation is flawed by the obvious granting of such use. **Why is this term seen by Group 70 as supporting this particular agricultural project and not more likely a PR attempt by themselves to favorably (not unbiased) represent HDF in this EIS endeavor?(Quote)"with high quality soil agricultural productivity ratings." Putting generalities to the side, what are the specific rating of this specific soil in this same area. Perhaps Group 70 should recognize the meaning of the term "null hypothesis" and compare the Aqua Engineer allowed use of the same land area as dumping ground for Class B bio solids near the proposed farm with that of HDF allowed use?**

The HDF banner word is "sustainability." It is a buzz word; difficult to put fact based parameters around. **What in this situation does it mean? Is there any indication that HDF is going to lower price on their milk?**

RJ 25

Will HDF lower the price on the milk produced at Clover Leaf dairy presently being purchased by them as Mr. Whiteside has just done to his Big Island dairy prices? Price of product is the problem and not sustainability. No situation can actually occur in the islands that cuts milk availability/sustainability which wouldn't also cut all other resources including power loss. What alternate uses for this particular site were examined i.e. local food crop production for direct local use? With that use of Mahaulepu, it would be a true marker of one of many varied sustainability definitions.

Under the summary of page 2 in the HDF EIS PN is a reference "establish the herd of dairy cow over several years" The initial 700 dairy cows arrive inseminate through a method of sex determined means, which generally produces more heifers than male calves. In addition to the first 700, and within a few short months, there will be 700 calves mostly heifers; likely 400 heifers plus in number. The new heifer in order to produce milk has to lactate and she will, along with the initial 700 dairy cows, calve within 2 years. This geometric progression is hardly "several years" but will be far beyond a 2000 head count in less than 4 and a half years. **What is gained with the "veiling of intent", "over several years" language.** It isn't a matter of depending on other conditions. It is what it is by nature of dairy cow breeding practice. Along with a maximum 2000 dairy cow operation come 2000 calves. **Other than the mention of "calf sheds" nothing regarding the bull calf disposal is mentioned but questions do arise. "Calves are moved into open paddocks after 3-4 weeks" Does HDF mean just heifers? Where do the male calves go? What contracts/terms exist between HDF and local ranchers for dispensing the male calves among them? Will they be slaughtered when born? For what reason and for how long are the heifers in the paddocks? Will they be contracted out and off site for repurchase later? This spin off second industry adds much more than just another grazing/feeding concept. It requires far more than a one line statement . Explain all the factors, paddock space requirement, manure increase etc. that will be created if the heifer count is added to the mix of dairy cows being milked and dry cows totals. Have they been counted in the HDF total or is the HDF numbers given only for milk producing cows? At any one time after full 2000 build out, what is the general representative number of each category ie. milking cows ,cows that have recently given birth, cows with special needs, dry cows, close-**

RJ 26

up heifers, replacement calves and heifers? What number of calves does HDF accommodate with the calf sheds as described on page23 (new proposal)?

On page 30, a reference is made to drip tubing or tape. What irrigation expert or firm, and why would they indicated the use of drip tubing or tape as a method for an area where a 330 dairy cow "mob" will -in mass- be placed to graze for 22 hours on pod sizes from 3.04 acres to 4.03 acres? On a normal rain , with that load, damage or hoof penetration is likely. Was the fact that the dairy cow is walking in wet soils considered when selecting this unusual irrigation concept; one more sensible for row crops than a cattle grazing area? What dairy irrigation concept supports this method of irrigation under these actual conditions?

On page 54 3rd proposal- one reads "gun type application system to area outside the liquid effluent application" Those areas are on the fringe areas of the property .On page 54 Redacted and 3rd proposal HDF reference" the gun and their 65 foot radius of spray area will be moved around the paddocks" The first application method is a mounted end gun on the pivots, and the second gun system is hydrant mounted guns used in the paddocks. Some paddocks; almost the closest property to Mauhaulu Rd will be covered by the first method. Use of the 2nd system gun system in other paddocks sets aside the assurances and claimed precision of the VRI system of irrigation. It is a wrong and primitive solution. It literally cuts corners and should not be allowed. It is a rare reader that has not been hit by wind-blown sprinkler spray or mist from a gun type application. Water ways are in its path (See page 32 (canal/ditch) running through the lower right corner of the property A gun type irrigation system spraying effluent will with wind drift create a combination of pollution either by odor, mist or both. It is a high error primitive system never used when sensitive areas must be protected. Its error rate is high and effluent scatter is at the whim of the wind. With sensitive stream areas near there should be no error variable in play. See as follows: and substitute the word "effluent" in place of "chemical "Western Agri Res Center PO BOX 1342 BLACKFOOT, ID 83221Performing Department

RJ 27

(N/A) Non Technical Summary

Application of chemicals with irrigation water is a widely adopted practice with center pivot irrigation systems, however, the standard practice of chemical injection at a constant rate results in systematic chemical application errors ranging from 7 to 22% for center pivots equipped with a corner watering attachment and/or an end gun" **Is this a important concern to consider? Does the application error mean amount of chemical (effluent) being distributed or include errors in pattern distortion? All solid research on sprinkler efficiency mentions "minimum of pattern distortion" What does that mean? What about "minimum" reflects zero distortion? Does it refer to distance as a variable not a fixed precise measurement ? What error variance was considered by HDF?**

It appears that the only set number given for off set allowance of a gun irrigation system use is refers to on page 96 2nd to last paragraph. That paragraph refers to "damage to structure" ie."Spread the effluent no closer than 50'feet from open water sources when applying liquid effluent with an effluent gun traveler. That system is defined as." The big gun" sprays a huge stream of water high in the air during irrigation, which is very susceptible to wind and evaporation losses - up to 30% or more in most cases. HDF has touted the new Zealand model, yet in "dairynz.co.nz-A farmer's guide to managing farm dairy effluent tells us" Some 'add on' effluent sprinklers to pivots i.e. guns have very poor distribution uniformity. " **What is different with HDF use of gun irrigation? Can the gun irrigation concepts be seen as a reasonable irrigation method for any area where water ways are close and boundaries are tight? What are considered appropriate set backs for each gun type. Why and What are these setbacks in feet? Has HDF indicated and defined what offsets and amount of property is within those offsets.**

RJ 28

What HDF usage is intended for the Canal/Ditch as show on page 9 and 32 (last proposal) and explained on page 7.

Can HDF paddocks marked M and S (Manure and Sludge) on page 8 be used as a receptacle for sludge on these paddocks- at random- and receive an unknown level of Sludge on an "as needed" basis and still meet a specific nutrient application level for the paddocks involved?

Given the now known soil conditions(see NRCS Customs Soil Resource Report for Island of Kauai Exhibit D), why has HDF determined a 20 ton Kikuyu yield is possible (see the "Is Kikuyu" reference on page 56). What field tests support that yield level on all grazing pods or is it yet on a theoretical "hope for" basis?

Although "Kikuyu- Guinea grass" is mentioned in the HDF EIS PN page 2-2. It was never mentioned in the last HDF proposal. It is a different nutrient. Will the EIS review confirm this grass combination? Why would Group 70 have nutrient information not framed in the submitted proposal? Is it a typo? Should it have been indicated earlier? How does that affect all other nutrient data? What other changes have been made in the basic parameters of the dairy concept? Will all changes to their last proposal be made public and in what manner? What agencies are now aware of the changes?

RJ 29

HDF EIS PN Kauai Ronald John

Fourth series of comments –questions and concerns

Quote–page 51- first HDF proposal. "The higher altitudes that feed the reservoir from (Waita) receive very regular and very large amounts of rain." From the center of the Waita reservoir to the HDF milking parlor is 3278 yards. The highest part of the mountain range behind Waita reservoir and Mahalepu is to the NNW end corner of the Mahalepu property and approx .2200 ft. Haupu at the NNE is 2600 feet. In the above sentence is the admission of "very regular and very large amounts of rain." **In what manner is this large amount of rain (coming from the high mountain range surrounding the HDF property- and inside a Horseshoe fashion)-kept from running through the manure covered field directly into ditches and streams traversing the HDF property .Will surface runoff occur ?Does this downhill run off end at the ocean. Was this known? Was it planned? If not why was this certainty ignored?**

Quote: "It is commonly believed from recent history that Kauai lays in a more vulnerable position than the other islands. However, in his recent analysis of Hawaiian hurricanes, Dr. Tom Schroeder of the University of Hawaii, Meteorology Department, concludes that every island has been affected by hurricanes and that no island is without risk. The randomness of nature plays a key role in which islands are at highest risk during any given hurricane. In 1988, Hurricane Uleki was poised to hit Oahu or Maui but passed to the south. Hurricane Iniki in 1992, could have hit Oahu or missed the islands altogether, but instead tracked right over Kauai"(Quote) Atlas of Natural Hazards in the Hawaiian Coastal Zone. By Charles H. Fletcher III, Eric E. Grossman, Bruce M. Richmond, and Ann E. Gibbs prepared in cooperation with **University of Hawaii, State of Hawaii Office of Planning, and National Oceanic and Atmospheric Administration** Geologic Investigations. Series I-2761

One of the most significant factors protecting adjoining areas from pollution or over run from effluent ponds is the gallon capacity of the ponds. Federal

RJ 30

regulations have guidelines and compliance expectations that must be met. Serious questions have been raised and DOH has sent HDF back to the drawing board for a redo of their effluent ponds capacity. The size and manner of construction is predicated on many factors one of the most prominent is the history of weather events that would create a breach of the ponds. A 24 hour 100 year review of storm participation was offered as proof of compliance by an HDF spokesperson 23 January 2015 (Quote Amy Hennessey Jan21/15 TGJ) "Our farm's effluent ponds are designed beyond the requires size to accommodate a 24 hour 100 year rain event." HDF uses the figure of 10.4 inches in a 24 hour time frame.

If only that was true- for their sake if nothing else-, but it isn't true.

A 100 years recap would take too many pages to outline this concern but just taking the high points of the National Oceanic and Atmospheric Administration data from 1950 till 2000 (50 years) will point out how much defining data was ignored or left out by HDF. Specific to Kauai: was Hurricane Hiki in 1950 with 52 inches falling in 4 days, Nina in 1957 with 20 inches of rainfall in 14 hours, Dot in 1959, with the eye directly over Kauai, Iwa in 1982 with all gauges down- listed as Heavy rain, Iniki In 1992 all gauges down- listed as Heavy rain (9inches at least). **if anything was left standing including dairy cows these Hurricanes would have filled the ponds and quickly brought them to an overflowing, runoff stage. What data supports otherwise?**

In regard to the endangered shearwater bird much has been said but until recently not enough done to protect this endangered species. A brief chronology follows:

"Hawaiian County Agrees to Pay Restitution and Modify Operations to Resolve Endangered Species Act & Migratory Bird Treaty Act Violations"

HONOLULU – The county of Kauai, Hawaii, has entered into a plea agreement to resolve alleged violations of the Endangered Species Act (ESA) and Migratory Bird Treaty Act (MBTA), the Justice Department announced today. The county today entered a plea of guilty to violating the

RJ 31

MBTA by taking That is killing or wounding, more than 18 migratory birds, specifically Newell's shearwaters (known in the Hawaiian language as 'a'o).

The Newell's shearwater is a threatened species protected under the ESA, and a migratory bird protected under the MBTA. The species is identified as endangered on the International Union for Conservation of Nature red list.

"According to the information, it has been publicly documented since at least 1979 that fledgling Newell's shearwaters are attracted to bright lights which often causes them to circle the lights and fly more passes across any nearby obstacles. This attraction may cause the birds to fly into the light or other obstacles near the light and thereby become killed or injured, or to fly around the lights until they fall to the ground exhausted where the bird may be killed by a car, predator or starvation." On approximately Aug. 3, 2005 and Sept. 16, 2005, as well as on various other dates thereafter, the county was notified by the U.S. Fish and Wildlife Service that its facilities, particularly the lighting at its facilities, were taking protected seabirds, including threatened Newell's shearwaters.

The county was given advice over a number of years that it could minimize takings by, among other things, shielding its lights.

The information specifies that during each of the past five years some Newell's shearwaters have been killed, or otherwise taken, by lighting at facilities operated by the county.....

. Starting with the 2011 football season for any night games all lights must be shielded and a similar escrow account funded.

LIHU'E — County officials announced Friday that work crews are in the process of manually re-activating the exterior lights at all county facilities to allow nighttime activities to resume.

The lights were manually disconnected just prior to the Newell's Shearwater fledging season from Sept. 15 to Dec. 15 to eliminate the sources of light attraction as part of a plea agreement between the county and the Department of Justice.

RJ 32

The only exceptions allowed were four evening Kauai Interscholastic Federation fall football games.

Other mitigative measures taken thus far by the county to protect Hawaii's threatened and endangered seabirds include: installation of shielded lights at Vidinha, Kapa'a and Hanapepe stadiums, Iseberg Park, Peter Rayno Park and the Lihu'e tennis courts; training on the cultural and ecological importance of the seabirds and bird-friendly practices for all county employees; and a monitoring program with respect to endangered seabirds.

At all other facilities, the lights must be inventoried and measures must be taken to minimize and monitor for takings, all on a specific schedule. As of 2011, if such facility lights are to be used at night during the fallout season (Sept. 15 until Dec. 15), an escrow account of \$100,000 must be funded, with an option to add additional funds in increments. Again, transfers would be made related to any takings that occur, from the escrow account to one for use to benefit seabirds on Kauai. If and when the fund is exhausted lights at facilities with takings cannot be turned on at night for the duration of the fallout season.

The plea also provides that the county will make a payment of \$180,000 to partially repair the harm of past takings to an account to be established at the National Fish and Wildlife Foundation for use to benefit protected seabirds on Kauai, and a payment of \$30,000 to reduce the harm from anticipated future takings. within the period of probation and prior to the county acquiring an incidental take permit, to the Kauai Humane Society to augment its Save Our Shearwater program.

"The Department of Justice views the taking of protected wildlife as a serious violation of the law, and we are pleased that the county of Kauai is taking action to reduce the risk of harm to this threatened seabird," said Ignacia S. Moreno, Assistant Attorney General for the Justice Department's Environment and Natural Resources Division. "The county's action will enable residents to continue to use county facilities, while protecting this native species that is part of Hawaii's cultural and natural heritage."

RJ 33

The Endangered Species Act prohibits the unauthorized taking, including harming and harassing, of species listed as threatened or endangered. The Migratory Bird Treaty Act prohibits the unauthorized taking, including wounding or killing, of bird species listed as migratory.

The case is being prosecuted by the Environmental Crime Section, Environment and Natural Resources Division, U.S. Department of Justice.

The TGI on 29 Jan 2015 publishing a concluding cost to Kauai for lighting correctly and taking in the full needs of the shearwater at One million Nine hundred thousand dollars.

HDF is aware of the high numbers of Shearwaters nesting and flying in the Mahaulepu area of the farm. They are aware that the amount of lighting needed to effectively run the dairy through the night is high. They know they have a night lighting conflict. That conflict of needs must be resolved before or ever the lights go on. It requires a much higher response level than "were working on it" or "we care for the shearwater bird." What by detail is the HDF plan to protect this endanger species? If "shielding" is a remedy what exactly does HDF mean by that term? Describe in detail intensity, glare, range etc. Does the plan met the compliance standards now agreed upon by the county?

How can HDF have lighting bright enough for cows to walk safely each way from a pod, as much as a mile and a half in night time dark conditions, a lighted milk parlor area, a lighted surrounding area for other related activities, and at the same time, protect the endangered shearwater bird as legally demanded?.

The Mahaulepu area is known for gusty winds. Kite flying is a noted activity in this area. In this type weather, stability of a non-fixed or un-tethered object is at risk. In 2014 and on HDF Mahaulepu property a full pivot system blew over. The weather was of a moderate storm condition with wind gusts. This incident is fully known by the HDF farm manager Mr. Garmatz, and the New Zealand crew that was assisting construction at that time. This pivot system is a large, tall, 2 support wheel configured, and

RJ 34

heavy system of the capacity to cover over 100 acres in a 24 hour time span. This full "tip over" if occurring while spraying effluent would have created an uncontrolled spill. No shut off system reacts on a zero time elapse basis. All VRI systems have an error dimension. What, if any method exists, stabilizes this pivot system when a large random gust hits it? As this system is susceptible to wind gusts when they occur, if operating even if it only is moved, flexed or tilted, from the intend direction, effluent spray will be emitted in uncontrolled and unintended directions. How are the streams protected? Does the farm manager confirm this wind gust blow over incident? Would this type spill be considered under "In Case if an Emergency Spill Leak or Failure during Transportation or Land application" (see proposal page 100)? Why wouldn't these type spills be seen as a continual factor of use or a certainty over time not an emergency spill or accident? What is the upper HDF numerical limit of wind force uses to determine nonuse of the effluent irrigation system? The average yearly wind factor for Poipu is 16.2 mile per hour. It is higher at Mahaulepu.

Pivot 1 has a pivot range as measured by Google Earth 27 Dec 2013 from approx. 130 feet at the top North arc point to approximately 70 feet to the lower edge of the pivot circle. Application measures of effluent put down during one rotation appears to be beyond the intake capacity of some soil types. Will the EIS address this issue? What consideration is shown for up slope run off?. As these applications occur quickly does data support this method of application? At what rate? Will the EIS address the slope issue as it relates to rapid run off rate of effluent, irrigation water or rainfall creating stream pollution?

RJ 35

5th series of comments-questions and concerns

"Findings and Recommendations Natural Disaster Survey Report

Hurricane Iniki

September 6 - 13, 1992

Chapter 1. The Event and its Impact

Finding 1.1

"A small but intense hurricane struck the state of Hawaii during the afternoon of September 11, 1992. Although all islands felt the storm, the islands of Kauai and Oahu were most impacted. Seven persons were killed and about 100 injured; total damage was about \$1.8 billion. The south shore of Kauai near Port Allen took the brunt of the storm with wind gusts measured to 143 miles per hour (MPH) and water levels (a combination of storm surge and waves) nearly 30 feet above normal.

Finding 1.2

Because of the apparently weak construction of many buildings, estimates of wind speed based on building damage may be unreliable. Estimates based on other indicators showed sustained winds of 130 to 160 MPH especially in areas where winds are enhanced by terrain.

Recommendation 1.2.1

The NWS should encourage the State of Hawaii to review its building codes in light of the Iniki damage".
Coastal Management News page 1: HAWAII INCREASES RESILIENCY THROUGH HURRICANE FORCE WIND BUILDING DESIGN
STANDARDS

Page 2

"The Federal Emergency In reference to Management Agency (FEMA) supported the technical work for Oahu and Kauai. By mid-2008, all wind speed studies were completed and transmitted to the State Building Code Council (Council) and offered as technical amendments to the 2006 IBC. HCZM participated in this effort by helping to draft legislation that established the Council and serving on the State Building Code Committee, a predecessor to the Council. HCZM provided key testimony to the council, requesting automatic adoption of the wind standards as a part of the county IBC adoptions. The Council adopted the wind standards for all four counties in its final draft of the State Building Code (entering public review later this year), and required each county to use their specific wind

standards no later than two years after state adoption of the State of Hawaii as a Special Wind Region."

Were all HDF buildings including calving sheds, silo storage and feed storages reviewed and approved to meet these wind standards? What compliance data was given. If none please explain. What amount of wind speed/wind load were these structures approve to withstand?. Are the approving agencies deliberations and recommendations on this matter readily open for public review? Who approved them and when?

This dairy is an experiment. As so, it would require a specific set of contingency planning/ back up for a wide variety of events which might occur. **Fail safe backup assurance if you will. 30% of nutrient needs are provided by supplemental feeding from automated silo to trough feeding. .Electricity is required. The best of machinery breaks down. Then what?** In the ranch area I came from and based on prior experience those type needs were anticipated and set asides- be it hay or grain or other- were available. One can't recall a government subsidy program, as exists now, that made up for poor planning. Unusual weather occurring was a given, not an accident or emergency.

. In a larger purview ie. docks close, on island provider of nutrient supplies shut down; what is the time limit when this nutrient expectation can be meet without relying on off site delivery of additional feed supplies? Where does that restocking come from? These are just a few examples of an imperfect world.

Ulepono Initiative principal Kayle Datta, in an opinion posted in the Garden Island Newspaper 15 Feb 2015, used a California dock strike as an example of the need for their Hawaii based dairy. **Wouldn't such shut down be more crippling of a nutrient plan that require 30% of their feed from a state side feed source. If that USA dock strike became a real problem there are New Zealand dairies with milk to be exported. Can they also take care of HDF feed source needs?.**

No one is against sensible, data supported, properly sited and sized dairies. That definition does not support the HDF dairy concept nor it being sited at Mahaulepu. **What are HDF's fall back positions? In detail, what major problems could disrupt their ordinary procedures? With full 24 hour operations required, what company, factory, assembly line or any other system didn't at some point breakdown? What amount of down time can HDF handle? What is the remedial action for electrical**

systems outages or mechanical problems? The HDF concept requires a high number per hour milking count. Who milks the cow when the milking machine is off line. When the back up solar power system becomes inoperative or depleted then what?

The mention by HDF re: wind break" or shelter belt as defined in NCRS Code 380. as being "a multiple row planting of trees will be established... page 57)" begs the full meaning of this concept .No effective relief is gained by the limited HDF treatment of this requirement, nor does it appear there is room for such planting. **The primary wind direction in that area is from the NNW .Where then should a odor minimization wind break be placed? This area is a large concern being treated with little regard. A serious odor mitigation plan must be required. What is that plan?**

The Clean Water Branch Brown Water Advisories are part of the information that would validate runoff problems of the HDF site. Most of the source of that condition in the ocean waters of Mahaulepu Beach comes from streams or ditches traversing the HDF property. This condition is frequent and has existed for years when flood irrigation was the method of irrigating the Mahaulepu Cane and Taro fields. The beginning of the now certain polluted level of the brown water is not known. Those who visit the area know of the long history of brown water there. Many have filmed it. If proof of the now existing and continual runoff displaying the polluted ability of the HDF location is necessary, then rainfall data should be available. The TGI stated in an article titled "All Washed Up" (9 Dec 2013) "According to the National Weather Service Poipu registered 4.33 inches and Kalaheo had 3.76." This was of a condition of just a week before the article and when there was an abundance of brown water in the ocean off Mahaulepu Beach for multiple days. **From the data of Surf rider at that time, to the most recent findings of DOH it is definite that the "brown water was and continues to be highly polluted .Will this evidence be considered in the EIS examination of pollution issues?**

Question arise regarding the intensive "grubbing, grading, planting ,and major alteration of the landscape. ,New ditches and other trenching were began and finished before permitting. In a jump start and confident mode, it appears that HDF proceeded to do much of this type work before permitting was approved. Google Earth close up imagery Dec 17 2013 show an

RJ 38

intensive amount of field work completed over a third at least of the property from Mahaulepu Rd for approx.1800 yards north toward the back end of the property and west to east at a max point of approx. 800 yards. Planting efforts are shown and water channels have been already cleaned or created. It appears that added and improved roadways have occurred by December 17 2013. **Heavy grading is noted. In addition, field trials are mentioned as having been performed earlier than the permitting date. Under what permitting statute were all the alterations allowed, and at what date did such permitting allow HDF to begin active alterations of the site? Was Grove Farm/or the planning approving agencies aware of the extent of the activity? Does this possible pre-authorized beginning of construction explain the measured significant increase of nutrient, bacteria and sediment in the Waiolopi Stream?- pollution far in excess of state standards-and occurring in higher numbers as they began "work" on the property? Does HDF acknowledge significant pre- permit and present activity beyond statute limitations? What agency onsite inspections have been made- by whom and when? -Was compliance to HAR11-55-04 shown? Was a storm water NPDES permit obtained? On what date was it applied for? What dates was it issued? If not seen as needed- Why? Cite the statute that allowed HDF to disregard HAR 11-55-04.**

What "reclaim" or clean up regulations for building on previously contaminated /pollution laden sites prior to subsequent building and commercial use (even if by an ag related industrial endeavor) are required by federal, state or county requirements? If the present levels of measured pollution levels are not first mitigated, increased runoff and contaminants from the HDF addition of a significant higher level of possible pollution would be added to the present volume and level of pollution now being found. One would image the Clean Water Act is also involved. Please determine, review and list all "clean up rules covering site use of this existing polluted property." In this regard advise if compliance to that standard requires the HDF property to be pollution free before beginning. If not- why not?

It appears that the definition or perhaps the difference between point source discharge and non-point discharge is blurred by this new and larger expansion of on fields use of excess manure. HDF has attempted to show its need by data supporting effluent pond use for this concept. What isn't a

RJ 39

matter of opinion is the dumping of sludge on the M and S (Manure and Sludge) 82 acre Area at the lower left hand corner of the farm (less than 750 ft east of the Koloa Public wells).

HDF is a CAFO as designated by 40 C F R paragraph 412.15. The Clean Water Act 33 U S C in part would assert that this dumping of sludge at least would be in violation of this Act if not by its "storage use" i.e. "not needed" or "an addition beyond usage" but for the certainty of comingling polluted water with that of the Taro Farm. The Taro Farm located at the very bottom of the HDF farm site could become a convenient dumping area for effluent over fill or catch basin for surface water, and then the subsequent drainage to the Taro farm ditch system would run to the ocean (one source removed) as part of their operation.

Grove Farm has shown little hesitancy in removing tenants from areas need by a bigger tenant. The small approximate 13 acre Taro Farm as located, stands out as abutting and surrounded on three sides by HDF property. It is conspicuous by its presences and also by its disregard in HDF planning. That so termed private property requires flood irrigation yet abuts a sludge containment area containing 82 acres. Block F of 54 acres which is described on pp. 73 " are perceived as heavy, flood frequently and difficult to crop is also next to The taro farm. No indication of protection or concern for the Taro Farm is written, and runoff, over spray or intermingling of its water with effluent mixed water was not considered.

The Taro farm abuts Block F described as **heavy, flood frequently**" **"characteristically poor draining. This location raises not just interest and suspicion but justifiable questions. A written description re: the interaction, terms, and considerations made between Grove Farm, the Taro Farm and HDF needs to be examined and explained. That relationship should be clarified, including what barriers exist which would stem overrun either in or out of the Taro Farm. In that regard there should be provisions outlined in the HDF proposal for involving or protecting the Taro Farm from any type disturbance or incursion. What are these provisions .if none exist- Why not? What should be done to consider/ protect the Taro Farm?**

There is a high degree of confusion regarding whether the nutrient data, waste management data etc. is for the ultimate build out of 2000 dairy

cows Section 11-200-7, HAR, states:
"A group of actions proposed by an agency or an applicant shall be **treated as a single action when:**" The component actions are phases or

RJ 40

increments of a larger total undertaking. A proposed action must be described in its entirety and cannot be broken up into component parts, which if each is taken separately, may have minimal impact on the environment. Segmenting a project in this incremental way to avoid the preparation of an environmental impact statement is forbidden". **Are all elements of the plan developed on the basis of full build out parameters? Wouldn't all other action need to wait until the "larger total undertaking" is sent through review and permitting protocol?**

The geometric progressive buildup of calving from the initial 699 dairy cows will build quickly to 2000 AUs (Animal Units) on HDF property. Obviously an increment of heifers and bull calves, by that process will be grow progressively larger and reach the 2000 mark within 5 years. The next calving cycle beyond 2000 (14 -16 months) will progressively expand the number by that full 2000 amount. HDF will either sell or uses the heifers for additions dairy production. It will also be producing a high number of male calves for sale. **There is no indication of calf pen size enlargement or additional excrement from the calf pens into the effluent pond or additional excrement on the paddock when paddock containment is being used for heifer calves. The excrement of calves both in calf pen and on paddock must be represented. What are the amounts considered? Are they shown in the present proposal? That information affects all HDF computations from effluent pond size to nutrient plan. What is the procedure to cap the total number at 2000? Does that 2000 number include calves, yet lactating heifers, and dry dairy cows? The proposal as written is unclear and unacceptable without more definitive clarity on these multiple issues.**

No mention of "dry dairy cow" or "sick dairy cow" is given. Where are they pastured? Are they moved from paddock to paddock? Are they separated and how? Other than the one line on page 91 (last proposal) "Animal Mortality Management Plan", no mention of a necessary veterinary space location or the cleanup of such area is given.

Recently legal findings were made re: Kauai Bottling Company right to use the Waita reservoir water for commercial sales. Grove Farms testimony is through out some of the narrative. Pioneer has a claim to water (page 31 first proposal) from the pipeline water also used by HDF. If more is needed

RJ 41

by Pioneer HDF would have to acquiesce to their usage of the pipe line water usage if necessary. Quote pp 31 " the pipeline is unlikely to be able to supply required water for irrigation when Pioneer is in full off take." **The possibility that future legal action could cloud the entire water use of Waita reservoir use is evident.. This must be recognized in an EIS review and a consideration if HDF planning. Has it been? In what manner?**

Little if any data used to support the present concept is usable to support a Confined CAFO conversion or to start initially as one. See 2-3 HDF EIS PN What factors supports this alternate as a " viable" one? Why?

Page 5 -1st proposal under Design Consideration indicates "Cow races need crossing solutions(culvert and bridges) at three points over the stream which passes through the dairy farm" **No explanation of how the stream is protected from manure and feces deposited while traversing these cross over points exist. Are protective side curbs on these direct outlets provided? Both, at the approach to these culvert and bridges while on the bridges and at exit points, would require side barrier containment? Where does the excrement during these crossing go and how is it contained?**

There is a freshwater "Lake Pond" abutting the HDF property line (upper left corner and on pp20(Redacted proposal) shown as discharging into a "canal/ditch" traversing the property and then leaving the property just above the area marked milking parlor at pod 105. **No protection of that ditch from pollution from the cited gun style (65 feet range)effluent emission spray or other excrement spillage is given. Why?**

Given a 2000 number of perfect automated cows and perfect systems working at max level, the time to transition a mob of 300 cows both up to the milking parlor, milk and feed, and back to that same pod relies on human workers and with that less than perfect variable, it is questionable that all the perfect cows could be milk in the time required for 2 milkings per day. Add in the slow walking dairy cow of reality, carrying a full udder of an average 110 lbs weight as she goes to the milking parlor and down time becomes a serious draw back of a scheme based on what might work for at a Confined CAFO setup. No rancher nor any one who has trailed cattle

RJ 42

would tell you otherwise. If two mobs are grazing on pods near one another you can not get the first of the two mobs of 300 back to its same pod (most pod distances are at least 800 yards from the milking area and many a mile away) while at the same time bring the next 300 cow mob up the same raceway. **This is not "3 little pigs going to market", but 300 dairy cows strung along "walkways and races" 16 to 20 feet in width (page 21 last HDF proposal) and often in poor, sloppy, weather. This concept won't work .At this time a reality based plan must be defined and explained. What is that plan?**

Waste Utilization-Field Office Technical Guide NRCS Section IV

Where the residues of energy production are to be land-applied for crop nutrient use or soil conditioning, the criteria listed above shall apply.

CONSIDERATIONS

The effect of Waste Utilization on the water budget should be considered, particularly where a shallow ground water table is present or in areas prone to runoff. Limit waste application to the volume of liquid that can be stored in the root zone. Agricultural wastes contain pathogens and other disease-causing organisms. Wastes should be utilized in a manner that minimizes their disease potential. Priority areas for land application of wastes should be on gentle slopes located as far as possible from waterways. When wastes are applied on more sloping land or land adjacent to waterways, other conservation practices should be installed to reduce the potential for offsite transport of waste . It is preferable to apply wastes on pastures and hay land soon after cutting or grazing before re-growth has occurred .Minimize environmental impact of land applied waste by limiting the quantity of water applied to the rates determined using the practice standard Nutrient Management(590) for all waste utilization. Consider the net effect of waste utilization non greenhouse gas emissions and carbon sequestration. "

It is difficult to examine the HDF proposal and find really based concepts that effectively meet these NCRS criteria. Some of the NCRS criteria have been simply ignored in the HDF proposal, and that is a significant concern. By field elevation data obtained from Goggle Earth one finds a number of varied field level elevations within the overall 100 ft elevation decrease extending from the northern most end of the HDF property to Mahalepu Road. Measuring across the fields- West edge to East edge- multiple

RJ 43

undulations are noted and as varied as 60 feet. These elevations are readily verifiable by Google Earth. The underlined and stated issues above are not addressed properly. Some are skewed outside the stated parameters, others are ignored. Shallow catch basins and pivot movement obstructions are apparent. "Consider" was never meant as being "were thinking about it." The EIS, for purposes of clarity deserved by all, must clear up all the generalizations and non-descript vagary.

The HDF proposal should have been characterized by and recognized as displaying appropriate data based planning. It does not meet that threshold of examination. What group of agriculture experts would sign off on a "full blind review" of this proposals content? None of many shown this proposal, even with "Group 70" displayed on the cover, found it of reasonable content. In what manner and by what data are these concerns now explained and addressed? NRCS had clarified in writing that they did not, as claimed by HDF in public presentations, PR press releases, and written communication and in multiple time in each manner "Approve" the proposal. It is evident also that NRCS was too quick and not thorough in their examination of the proposals concepts and support materials.

These issues must be resolved in a professional, detailed, thorough and reality based manner. Rigorous examination of such serious issues is essential and required. A concrete data based explanation of all the above underlined requirements is requested by line item evaluation. It should include but not be limited to field elevations and drain slope numbers." Have Faith" or "Trust Us" is not the review standard nor in matters such as this, will promises suffice.

On page 12 and 13 last proposal HDF identifies the predominant 3 soil types on the HDF property as "Poorly Drained." 8 soil types, though significantly smaller in acreage size, are identified as "Well Drained" One soil listed as rRK is listed as "Well Drained although shown as having a 0.00 to 0.06 Ksat capacity and identified as 'Rock Land. On page 64 these soil types are bundled into 23 CMUs (Conservation Management Units)**These CMUs are used for nutrient planning purpose yet many are of different total sizes, have within them different Ksat levels and varied soil types. How does HDFs nutrient plan successfully accommodate these differences? What is**

RJ 44

the expected procedure in this area? Will the EIS review process examine the question of whether nutrients overwhelm the absorptive capacity of the soil, and either runoff or will be leached into the groundwater? The maximum allowable rate of application (inches per hour) to prevent runoff depends on the intake rate of the soil. This basic underpinning of application rate is continually conflicted by HDFs own indications. Will the EIS review this specific compliance need?

Conspicuous by its presences and also by its disregard by HDF planning is a Taro Farm in the lower left hand quadrant of the property This private property requires flood irrigation yet abuts a sludge containment area containing 82 acres and block F of 54 acres which is described on pp73 "are perceived as heavy, flood frequently and difficult to crop. No indication of protection or concern for the Taro Farm is written, nor is runoff, over spray or intermingling of its water with effluent mixed water considered in the HDF proposal. Why not? What should be done to protect the Taro Farm?

HDF on page 73 explains Block F-Special Management. They restrict the Block size to 54 acres. Abutting and continuing north of Block F are Pod 211 through 218 and still connected farther north include Pod 121 through 124 and to their west Pod 101 through 104. All these connected and additional pods are of like soil types. **Why is the total area of connected like soil i.e." heavy, flood frequently" "characteristically poor draining" treated in a different manner**

RJ 45

HDF EIS PN- Kauai- Ronald John
6th series of comments-questions and concerns

A general rule but specific to the HDF flow of multiple proposals is: "When a significant and substantive change or changes occur in a proposal document creates a significant and substantive difference in the body of the proposal (multiple data points/factors) the entire approval process must begin again." Was West Kauai Soil and Water Conservation District notified that the proposal as presented contained directly opposite soil ratings? After that acknowledgement did West Kauai Soil and Water Conservation District approve and NRSC examine the most recent proposal? What actual data should have been considered by these agencies? What adjustments did DOH have to make when the true data was given to them?

There is a conflict by nomenclature misrepresentation implicit in The HDF statement page 7-2.2.1 Quote "The drainage ways within Mahaulepu Valley and within the project-----these canals and ditches flow---There are other water ways than ditches and canals on this property, HDF calls them "unnamed drainage way" Why wouldn't they know the names? Actually two historical streams (Kapunakea and Waialaa) consolidate into one and enter the class A ocean at the end of Mahaulepu Beach near the Makawahi Cave Reserves. The HDF type of generalized terminology is replete throughout the proposal and should be noted and considered in the EIS review.

In earthquake planning for retrofitting or design of new buildings the terms "worst case scenario" or "significant events" are primary to setting the parameters to be met. From Waste management through Nutrient plans HDF appears to misunderstand that basic protective need. HDF proposal language speaks in terms of "average" There is nothing precise in that term. Words like "assume" have no place nor is a sensitive, critical factor presented as "observed. "Average" is not "actual." "Average" is an artificial indicator of a wide bandwidth of conditions not one specific condition only. You do not develop plans for developments such as an experimental dairy project based on average, generalizations, or probability but build on a standard of "possibility of" and specifics. Does HDFs proposal content met that necessary threshold and does EIS reviewers see this specificity as necessary? The bar of acceptance for

RJ 46

approving the contents of their proposal data would be below any normal standard of acceptance if a dairy design of this nature was given a permit based on such loose linguistic presentation."

. When specifics are given such as page 39 first proposal- sentences like "Buried pipe will be installed at sufficient depth below the ground surface to provide protection from hazards by traffic loads, farming operations freezing ,temperature-----"this level of document preparation speak of "cut and paste" and no attention to content applicability. "Freezing temperature" this after 5 years of studying? This parameter for a Hawaii based dairy farm? Isn't specificity and accuracy required in proposals of this nature? If anyone is to find legitimate support for this project, conclusory assertions must be replaced by data and that data being interpreted correctly. At this time the deficits in HDF's presentation are obvious and if left to stand unacceptable. It is a seriously flawed attempt pointing to little academic discipline and an abundance of unconcern. What should/can be done to gain the precision required? In itself this proposal is as flawed as its concept, and by its self should be rejected. On what merit is this proposal deemed acceptable by any objective reviewer?

What can one determine from the admission of Quote pp. 53 first proposal? "Water application will be at rates that minimize transport of sediment, nutrients, and chemical to surface waters, and that minimize transport nutrients and chemicals to ground water". From "establish and operate the first zero discharge grass fed dairy" in next breath to "minimize transport" to surface waters and ground water. Is this admission not clear in its intent? Minimize does not enhance nor describe compliance to "zero discharge." What does minimize represent to HDF? What outcome is unclear in that admission statement?

The continuous effluent bath of the pods already holding a significant amount of fecal material will over time significantly affect the water systems and ground water. **That is a certainty as is the eventual**

RJ 47

nonproductive capacity of the soil. Why is this ignored? What information or data in the proposal support a different conclusion?

Quote New Zealand Dairy Farm Guide "Sloping land (>7°) or land with hump and hollow drainage refers to soils which are gently rolling to steep. Also includes soils which have been humped and hollowed. The main risk is runoff on these soils. Management tips: application depth must be less than soil water deficit and application rate must be less than soil infiltration rate" Page 12 HDF proposal lists 7 of the soil types having slopes in excess of that rule. What does HDF do to rectify this discrepancy in irrigation concept? Was humped and hollowed contouring done on the HDF property? Were contours sloped toward the water outlets when grading was being done? What contour maps were used during the grading of the HDF property? What contour changes were made? Prior ground elevations are available on Google Earth. What does present satellite imagery show?

The HDF pivot system is a large, tall, 2 support wheel configured, heavy system of the capacity to cover over 100 acres in a 24 hour time span. The full "tip over" of 2014 if occurring while spraying effluent would have created a uncontrolled spill. No shut off system reacts on a zero time elapse basis. All VRI systems have an error dimension. **What, if any method exists, stabilizes this pivot system when a random unpredictable gust hits?** As this system is obviously susceptible to wind gusts when they occur, even if only moved, flexed or tilted, from the intend direction, effluent spray will be emitted in uncontrolled and unintended directions., How are the waterways protected? Does the farm manager confirm the 2014 wind blow over incident? Would this type spill be considered under "in Case if an Emergency Spill Leak or Failure during Transportation or Land application" (see proposal page 100)? Why would the 2014 blow down not be seen as a factor common to its use not an accident? What is the upper HDF numerical limit of wind force uses to determine nonuse or "stand down" of the effluent/ irrigation system? The average yearly wind factor for Poipu

RJ 48

is 16.2 mile per hour. It is higher and more varied as you go up toward the mountains. What are those readings?

What are the weight and size dimensions of the pivot system wheel sets, their width and weight per unit? How many wheel systems per pivot and what is the total weight load on an individual wheel section when in full operation. What is the distance to the outer gun system and what is the tracking speed of the outer pivot? Wheel rutting is common to all pivot systems. It is more so when one is as large and heavy as that HDF is using. What are the single wheel width and weight dimensions? Within a short time of use distinctive tracking/rutting paths will occur. When either prepped as a hard surface or becoming one when in the clay areas of the fielding- how will rutting be prevented and runoff not occur from these tracks? As these tracks become fixed, permanent pathways, they will become quickly visual and distinct. They will become multiple miles of circular conduits where any irrigation water or effluent can be carried away. These certain depressions will either hold or runoff to other areas .if the tracks are hard surfaced by design then they now become pathways/walkways, much as raceways etc. They, by known function, become "discharge" areas. If unintended they will, if not hard surface designed, become depressions holding standing water in stagnating pools. If accessible, animals of all types drink from them. As much or more than walkways raceways etc. these certain channels must be considered and runoff to them and beyond controlled. Will the EIS address that need? There is considerable fluctuation of elevations determined by Google Earth Dec 2013 which not only impedes a pivot system but can as well stall or shut one down. What is the shutdown emergency reaction time? Why did it not work in the 2014 tip over? How many wheel sections are in Pivot 1 and Pivot 2? What is the circumference of the pivot circles? What is the combined total mileage length of the different pivot tracks?

Do the pivots/ wheel systems cross waterways? By what means? A pivot system cannot be shielded in such manner that pollutants aren't

RJ 49

carried and dropped into waterways from the body parts/hardware of the pivot equipment while passing over it. The entire functional reality in this context must be evaluated. What is the lag time between signal and full shut off (no residual drip)? Is each section of the pivot system pressure regulated? What is the lag time from shutoff signal to pressure to zero on the outgoing flow?

In trials ran on VRI equipment (ASABE Technical Library) a catch can test on a SS-VRI equipped pivot system resulted in evaporation and drift loss at an average of 9.3% and ranged from 1% to 19 % the question again is: Given that data how can zero discharge be assured?

Page 54 mentions a " 4 inch underground pipe to a number of hydrants" for caring suspended solids to the paddocks. 4 inches under the ground-ground now disturbed/loosened by the burial of pipe and, heavy weight pivot wheel systems crossing these pipes. Can that pipe withstand the weight load of a pivot system wheel section? Is this gun section limited to the 82 acres M and S area only or all areas "outside the liquid effluent application" (page 54 new proposal). What paddocks by number are involved in this concept?

At this point of time, (4Feb 2014) measured levels of pollution have been determined at multiple levels above a safe number and these polluted waters running into the ocean affect the "protect conditions" exactly as described above. The reason for the disregard/disconnect from regulatory statues listed above and the certain continued pollution must be explained in reality based parameters. In that context HDF must be explained, beyond the usual generalities, how they intend to meet non pollution requirements.

There are multiple general explanations intermingled with varied specifications of acreage that will be used for grazing/paddock . With all setbacks considered- raceways, milk parlor silo, storage, graveyard etc. What is the specific total number of acres that a dairy cow will

RJ 50

generally occupy for grazing purposes only? Please detail those pods and acre amounts?.

With the average mortality rate given dairy cows what data justifies and supports the small ("about 4400 sq. feet") only set aside (see page 101)? Two thousand dairy cows and a tenth of acre "Animal Cemetery " is not a sensible projection. The average mortality rate of dairy cows at this time is in the 5% yearly range. "The new and higher rate may be due to regulatory change in the United States, when at end of December 2003 new regulations required euthanasia of downer cows to prohibit use in human food supply channels(USDA, 2003). "That change would be expected to shift DHL reporting of reason for lactation termination from "sold for slaughter or salvage" (formerly "sold for beef")to "died" (Animal Improvement Programs Laboratory,2007), as noted by Fetrow et al. (2006)". On page 12 and 13 Table 5 One category displays "Depth to Water table" That soil category of the Animal Cemetery is shown as greater than 80 inches .On page 97 HDF indicates "Pits will never go deeper than 8 ft (96 inches) This is but one example of disjointed, multiple and serious conflicts in their own data. For all they know that's at a water level or close. What burial depth can one assume will be used.?

At full build out of a 2000 dairy cow, the annual 5% mortality rate would mean approximately 100 burials a year in a space no bigger than most single family building lots .What explains this discrepancy in space requirement needs ? In addition, the placement of the HDF "Animal Cemetery" is near a stream, and in situated in an area where mountainside rain runoff is peak. None of this placement makes sense and it must. What should be considered as an appropriate site and size if the Animal Cemetery carcass disposal is as planned? Given storm water infiltration: at the level of burial depth when does leaching of the decomposing carcasses occur and percolate to the ground water begin? Do the math: 2 ft wide- 5 ft minimum length -3 ft separation of burial site. Where and when does HDF start the next site? Was any conversations held with any slaughterhouse owners re: disposal of the dairy cows? Was conversations re: this matter- held with slaughterhouse owner Willie Sanchez? What are HDF slaughterhouse needs? For what purpose will HDF use a slaughter house?

RJ 51

In seismic planning for retrofitting or design of new buildings the terms "worst case scenario" or "significant events" are primary to setting the parameters to be met. From Waste management through Nutrient plans HDF's presentation appears to misunderstand that basic expectation. HDF language speaks in terms of "average" There is nothing precise in that term. Words like "assume" have no place, nor is a sensitive factor presented as "observed." "Average" is not "actual" nor does it bear the weight of requirements that must be based on actual measurements. Average has a wide bandwidth, not one singular condition only. You do not develop plans for developments, such as an experimental dairy project, based on average, generalizations, or probability, but build on "possibility of" and specifics. If anyone is to find legitimate support for this project, conclusory assertions must be replaced by data and that data being interpreted correctly. At this time the deficits in HDF's presentation are obvious and if left to stand unacceptable. **What should/can be done to gain the validity and precision required for this proposal?**

The well system serving Koloa and Poipu is not as depicted (Quote Page 12" HDF proposal) **"The Koloa F well is located 1/2 mile away."** The purpose of that HDF statement denies reasonable explanation and frankly is suspect. Well F and other public wells in the same area are within 350-750 feet. There is a host of questions: **How and why can such mistake in measurement be committed? Were any water officials consulted? When? With whom, and for what reason? Did HDF know that the County wells provided water for all of Poipu and most of Koloa? What EIS reviewers will be involved in reviewing this area? The same footprint over the aquifer where the well are sited is shared by the 82 acre Manure and Sludge area of HDF. Were the county officials made aware that abutting the actual well system was 82 acres of drip system irrigated manure and sludge (M and S) not only next to but on top of the ground water aquifer feeding those wells? The questions now listed concerning this matter are but few of those in this specific area that require scrutiny and factual explanation. **Why in particular was "1/2 mile" used as an indicated offset distance figure from the wells, and not the true figure?****

RJ 52

On page 54 3rd proposal- one reads "gun type application system to area outside the liquid effluent application" Those areas are on the fringe areas of the property. On page 54 Redacted and 3rd proposal they reference" the gun and their 65 foot radius of spray area will be moved around the paddocks" The first gun type is of mounted end guns on the pivot ends. The second gun system is hydrant mounted guns used in the paddocks. Some paddocks; almost the closest property to Mauhaulu Rd will be covered by the first method. Use of the hydrant mounted gun system in other paddocks sets aside all the assurances and claimed precision of the VRI system of irrigation. It is a known wrong and primitive solution never to be used to spray potential pollutants in sensitive areas. It literally cuts corners (see 442-page 8 FOTG "irregularly shaped pen areas that are impractical to treat with a sprinkler system") **How many of the paddocks are irregularly shaped?** Gun sprinklers should not be allowed. It is a rare reader that has not been hit by windblown sprinkler spray of gun type. At the Mauhaulu site are multiple water ways within a sprinkler span. For example (See page 32 (canal/ditch) running through the lower right corner of the property and which they will irrigate by pivot end gun use. A gun type irrigation system spraying effluent will with wind drift create a combination of pollution either by odor, mist or both. Its error rate is high, it precision and sprinkler uniformity low. The sweep is outward, frequently random and its scatter at the whim of the wind. With sensitive stream areas nearby no error variable should be in play. **Given the multiple streams proximity and irrigation systems What data exists that would support this method as a reasonable irrigation method for either irrigation application concept HDF intends to uses? Why?**

HDF must demonstrate how they will comply not just they will comply to irrigation standards. Under NRCS FOTG Sec. 4 page 6 through 9 they must specifically relate each of the requirements to their field irrigation concept, and to the hardware used for such irrigation. HDF must demonstrate an understanding of and compliance to all regulations governing dairy operations. That compliance must be written, and open for EIS review.

RJ 53

The HDF impending purchase of Clover Leaf Dairy on the Big Island, should be considered under “cumulatively has a considerable effect” language or “commitment for larger actions” criteria 8 of the ESI Significant Criteria. Will this matter be reviewed? This purchase is HDF’s second effort toward an announced 10000 dairy cow constellation . That figure points to a additional 10000 calving number every 14 to 16 months and higher each lactation period. Quotes by the present owner-Ed Botelho raise serious concern. The following quote is part of an article “ Dairy farming in Paradise *Dairying Across America: Hawaii*”

“Our land runs right down to the Pacific Ocean,” said Ed Botelho the farm’s operator. “On a clear day, you can see some of the other islands. During the winter we often see whales swimming by.” (2 full color photos were included with captions)
The admission (“Our land runs right down to the Pacific Ocean,”) underpins the worst ecological/ environmental disaster New Zealand has faced in modern history.

The picture as captioned in the article is of itself revealing (.A single dairy cow grazing as a giant cruise liner passes by. However, what it reveals is not to many a magnificent, bucolic scene depicting the grandeur of spectacular agricultural setting. It could as well illustrate the greatest ecological/environmental disaster yet experienced in New Zealand and certainly all over England, France and the America’s to name but a few of those area devastated by a lack of environmental concern. It could represent the single rule we are learning much to slow. “Large consolidations of cattle enclosed in confined spaces next to or over water bodies can create serious and lasting pollution.”

Under the “prevent language” of 344-1, In what manner does one alert/involve government agencies regarding this pollution possibility? Does DOH have stream pollution readings of the Kahalo Ditch or at the ocean as the stream run off leaves the Clover Leaf Dairy? All major dairy pollution started with a small amount of dairy cows. Hawaii must take in advisement the yet unstudied environmental impact of this collective HDF effort. What regulations cover the cumulative pollution possibility of this next step toward an intended 10000 dairy cow build up? 10000 dairy cows mean within 14 -16 months 10000 calves. Then what?

If this uncontrolled concept can ruin New Zealand(an island) as it

RJ 54

has, the Big Island area size pales in comparison.

Prior to HDF’s last proposal submittal a “NRCS Customs Soil Resource Report for Island of Kauai Hawaii” was published. Interestingly it covers and is limited to the Mahalepu HDF property site. It points out clearly what HDF should have noted and considered in the last submitted proposal. It has been indicated by NRCS that the reason for that research report at that time and requesting agency are secret and protected, yet no search of the series 401 regulations have been found that impose such secrecy/privacy protocol.

General Manual

Part 450 - Technology

See401.A.1(450-GM, Amend. 9, March 2000)Part 401 - Technical Guides

Subpart A - Policy and Responsibilities

Who requested the above referenced specific NRCS Customs Soil Resource Report for Island of Kauai? When? When was it given to the requesting party?

If HDF was aware of this data, an intentional disregard for the data contained in the NRCS Customs Soil Resource Report for Island of Kauai Hawaii has occurred. That significant “error of omission” requires open explanation. Will the EIS process evaluate this concern? If HDF was the requesting party then ignoring its content creates a serious breach in protocol governing multiple governmental agencies. The afore mentioned report is an objective analysis. It points out with critical science based data why HDF is not a project suited to this particular site. Did HDF have knowledge of the existence of the NRCS Customs Soil Resource Report for Island of Kauai? If not –Why not? Has effort been made by HDF to now integrate or respond to the data in this report? What efforts by detail have been made?

No expert, shown this report by the writer, including one former farm loan bank officer, have found it as supporting- in any way- this concept- at this site. On the contrary the report is a stand alone analysis of which no one could deny its data or impact. One reviewer with shaking head ask ‘what is their real intent for the use of this land? Is the financial backing source- Pierre Omidyar- or Kyle Datta aware of the findings contained in this report? Is Pierre Omidyar aware of the EIS review or this report? Why was its clear, concise findings ignored? Why even now is it ignored,

RJ 55

not acknowledged or considered by HDF in formal presentations?
What data based facts can outweigh the burden of evidence contained in the NRCS Customs Soil Resource Report for Island of Kauai? Will the EIS take in consideration the full import of this report? In what manner and by which of the review agencies will it be considered?

In the area of professional preparation: has Group 70 ever developed or evaluated a Waste Management Plan of a dairy similar to the one proposed by HDF? When? Where? What other dairies have they designed waste management plans for?

In closing: Proposals made to approving entities are to explain not to confuse. They should alleviate fear or tensions, assure that no damage or harm exists in what is proposed. Some include a clear validation of its need or necessity. This expectation was not met by the one now being considered.

Those of us voicing concerns are for reasonably sized and sited dairies. None of us believe Mahualepu is a legitimate choice. As there exists a difference between legal and ethical, there too is a difference between could and should.

Pierre Omidyar, Ulepono Initiative, and Hawaii Dairy Farms **should** do the right thing.

Dear Ronald O. John:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i

Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Ka'ena Clay Brown Variant at 29 percent, and Luualaei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite,

a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.1.6.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauai region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hatupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction

Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways;

only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal

area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling

system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas; and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the

cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be

healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will

benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Ka'ena Clay Brown Variant at 29 percent, and Lu'ulauei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasech Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawaii's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Mahā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures

include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEOCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Hawai'i Dairy Farms, LLC.
P. O. Box 1690,
Koloa, HI 96756-1690

Dear Madam or Sir:

I am responding for my wife and I to the Call for Inputs that will help to define the scope of the Environmental Impact Statement ("EIS") to be prepared during the coming months related to the proposed Hawai'i Dairy Farm ("HDF") in Maha'ulepu Valley, Kauai, Hawaii. We have the following concerns and hope they will be subjects of investigations during the EIS preparation:

1. We own a unit in the Poipu Sands condominium located in the Poipu Kai Resort situated just west of the Grand Hyatt Hotel and Resort. The trade winds generally come from the northeast which would bring any odors from the HDF through our property. As past Wyoming cattle ranchers we know of the odors that develop from a stationary herd of cattle. These smells are expected around ranches and other areas where cattle are confined, but are not expected in Hawai'i. If these odors transit from the proposed HDF it will impact not only our enjoyment of stays on Kauai but also income we obtain by transient rentals of our condominium unit. There is also the possibility (likelihood?) that the sounds of cattle mooing will be carried on the trade winds and heard through the day and night at the Hyatt and in the Poipu Kai Resort.

2. We have owned our condominium unit for 25 years and have enjoyed the Maha'ulepu Beach area during that period although we now hear that the waters in the area are unfortunately polluted, although investigations are underway to find out why and to try and recover the beach water quality. But this will possibly be impossible if cattle waste causes soil damage that permeates and/or transmits to the south towards and to the Maha'ulepu Beach. This we believe should be avoided to preserve the environment in and around the Maha'ulepu Valley and beach area.

3. The two concerns above would, if negatively impacted by the HDF, cause a large financial loss to the County of Kauai. With the ease of transferring information through the public domain using today's internet system, it would soon become common

knowledge that the south shore of Kauai is no longer the place to vacation and/or live. This would create a large hardship for current property owners within a few miles of the HDF facility (and likely throughout the rest of the south shore resort area), and would certainly cause very large income reductions at the Grand Hyatt Hotel and Resort. All of these financial impacts would certainly change the current economic welfare of the community south of Koloa, Kauai, Hawai'i, ... and a very significant reduction of County of Kauai's property tax revenues and State of Hawai'i GET and TAT revenue collections.

4. Finally, we are unaware of an environmental restoration plan should the HDF be allowed to proceed with their plans which eventually do cause unacceptable damage even though the damage was not anticipated.

These are just a few of our concerns as long-term owners of south shore property, property whose financial value would likely be significantly damaged by HDF operation. If this occurs, the Kauai's south shore area will certainly degrade and become drastically different than it is today.

Very truly yours,

Vince and Fran Jones

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4)2-9-003: 001 portion and 006 portion
(4)2-9-001:001 portion

Dear Vince and Fran Jones:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawaii at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawaii". The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luualaei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies.

In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NOISE: Existing noise conditions of the project site and the surrounding Māhā'ulepū valley area are evaluated in the Draft Environmental Impact Statement (EIS), along with anticipated short-term and long-term noise conditions associated with the dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai'i Department of Health (DOH) rules use the A-weighting sound network (dBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes. The Hawai'i Dairy Farms (HDF) site in Māhā'ulepū Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition,

occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 78 decibels or that cost a total of more than \$250,000. Mitigation measures to minimize construction noise will include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be

produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the

unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow

comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kālaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable

to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and

a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator

bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970 (CAA)*, amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards (SAAQS)* that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM_{10} and $PM_{2.5}$) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM_{10} is $2.01 \mu\text{g}/\text{m}^3$, well below the State standard of $150 \mu\text{g}/\text{m}^3$. The estimated concentration for $PM_{2.5}$ is $0.23 \mu\text{g}/\text{m}^3$, well below the Federal standard of $35 \mu\text{g}/\text{m}^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual

offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OHQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Hawaii Dairy Farm Comments for Planning Consultant

Dear John Overton and Group 70 International,

Thank you for sending the notice regarding the Preparation of Environmental Impact Statement for Hawaii Dairy Farms, LLC. We await the delivery of the Environmental Impact Statement with keen interest in reading its contents. We are vacation rental condo owners at Regency 512 in Poipu Kai and are concerned about the impact the dairy farm may have on the enjoyment and value of our property, and on the environmental well-being of Kauai in general.

Sincerely,

Gayle Jorgens and Stanley Wai

Subject: Hawaii'i Dairy Farms
 Environmental Impact Statement Preparation Notice
 Maha'ulepu Road
 Kaua'i, Hawaii'i

TMK: (4)2-9-003:001 portion and 006 portion
 (4)2-9-001:001 portion

Dear Jorgens, Gayle and Wai, Stanley:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawaii'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasc Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the

development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawaii'i Island), approximately 10 percent of Hawaii'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawaii'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

GROUP 70 INTL

To Whom It May Concern:

This letter is being written to identify the issues which need to be addressed in the Hawaii Dairy Farms EIS related to the New Zealand Method Dairy Farm projected to be established on Kauai's south shore at Maha'ulepu.

1. Procure an impartial party to conduct the EIS.
2. Assess the current levels of pollution in the soil, stream and ocean at Maha'ulepu.
3. Integrate the conclusions of the existing soil and water quality studies that have been done in the area.
4. Include the projected herd size into the EIS.
5. Address the lethality of the proposed effluent ponds.
6. Address the stench that will permeate the surrounding residential and tourist area and decimate our local tourism economy resulting in lost jobs and access to our pristine beaches in the area.
7. State the cumulative effects on the environment.

Thank you for the opportunity to voice my deep concerns related to developing this dairy farm at Maha'ulepu.

Please notify me of everything that happens on this issue in the future phases of the EIS.

Sincerely,

David Judd

Dear David Judd:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawaii Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawaii Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawaii Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawaii Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's experienced team of technical sub consultants that are well-known and qualified in

their respective fields of study. For this project, Group 70 is preparing the Hawaii Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP/N. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and

irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West-Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawaii." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Ka'ena Clay Brown Variant at 29 percent, and Luulualet Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies.

In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plascq Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kauai, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kauai.

The HDF project would contribute to diversification of Kauai's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kauai, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$6,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no

animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed

in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected

from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment

which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM_{10} and $PM_{2.5}$) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM_{10} is $2.01 \mu\text{g}/\text{m}^3$, well below the State standard of $150 \mu\text{g}/\text{m}^3$. The estimated concentration for $PM_{2.5}$ is $0.23 \mu\text{g}/\text{m}^3$, well below the Federal standard of $35 \mu\text{g}/\text{m}^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas.

and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

To: [HDF: hdf@hdf.com](mailto:HDF@hdf.com)
Subject: EIS, CIA/CIS, AIS
Date: Monday, February 23, 2015 4:04:19 PM

We attended the HDF meeting for EIS, aka "dog and pony show" (TGI, FEB 21, 2015) http://thegardenisland.com/news/local/dairy-plans-move-ahead/article_82bfc036-b986-11e4-ba30-3b4dd074ffa2.html in Koloa town, held only 3 days prior to the deadline for comments. It felt more like "snake oil" salesmen, attempting to sell their magic Elixir (milk) at a traveling circus!

More troubling was what I witnessed:

The station presenters, repeatedly instruct their "scribes" as to WHAT to write, transforming many comments and concerns into watered-down questions.

For example:

I asked "Why is Water not considered or included In the Cultural Impact Statement (CIS) / Cultural Impact Assessment(CIA)?"

The scribe wrote "Is water included in the CIS?"

The latter requires a simple No for an answer.

I observed this occur more than once.

Also, I QUESTIONED ALL OF THE STATIONS, of which there were four: Water, Air, Cultural and Waste management.

A bit puzzling, as there many other triggers for an EIS, as in ENDANGERED SPECIES CONCERNS, or PUBLIC HEALTH CONCERNS. Neither had a presenter to address these important issues.

I therefore believe and request that another unbiased EIS evaluator act in the capacity of consultant, not Group 70.

I brought up SUB-SURFACE CONSIDERATIONS, as related to AIS, CIS/CIA, Water and Waste management.

Also we informed the Oahu presenters of the incredible WINDS we have here on the southshore, the air is bad enough from VOG.

And what about the COWS in the event of a Tsunami? We have evacuated three times in the past three years, there is not an emergency plan is HDF proposal.

Participants were also encouraged to LEAVE the Comment sheet provided. Will these REALLY be addressed in the EIS, or just published, written down on paper, as THEY STATED?

As for the proposed Dairy, we have many concerns that need to be addressed in the EIS.

Please be advised we have filed a report with DLNR, Aha Moku Advisory Committee, of which Billy Kaohelauli is the KONA MOKU for Manakalanipo (Kaua'i). Document attached, dated 12/08/2014.

PLEASE consider this information, as it has been currently filed with SHPD. Maha'ulepu is a SACRED SITE, and must be protected for future generations.

Appropriate, sustainable farming is what the IAL designated lands were meant to provide in Maha'ulepu Valley, not an inappropriate INDUSTRIAL venture. The unique soil type (grey Hydromorphic with high clay component) is perfect for Kalo (Taro).

Other appropriate crops would also fare well in this valley.

AND THEN THERE IS THE WATER:

THREE wells that provide our drinking water for our community, uncomfortably near their proposed location.

HDF cannot guarantee these wells will not be contaminated, or what they will do if they are contaminated.

The Close proximity to our beautiful undeveloped beach is also at great risk of contamination, as well as the entire FRAGILE REEF ECOSYSTEM.

There is already evidence of contaminated Waiopili spring and in the Maha'ulepu / Gillian's Beach ocean area (Blue Water Task Force/ Surfriider Kaua'i).

THIS MUST BE ADDRESSED IN THE EIS.

Please find the dairy another location, preferably in another STATE.
Sincerely,

Billy Kaohelaui'i (Kona Moku, Manokalinpo)
and

Terrie Hayes

Manokalanipo (Kaua'i) - Kona Moku Report Form GROUP 70 INTL

This form is used for areas and ahupua'a within the moku of Kona, Manokalanipo (Kaua'i) when an issue or concern impacts a natural and cultural resource within its specific land or ocean district. Ahupua'a are: Kona - Mahaulepu, Pa'u, Wehiwehi, Koloa, Aepo, Lawai, Kaitaheo, Waihanawa, Hanapepe, Kupua, Makawali, Waimoa, Kapena, and Kekaha.

Date: 12/8/14 Case no: _____

Name of applicant (or Hui, if applicable): Llewellyn (Billy) Kaohelaui'i, Aha Moku (Kona District)

Address of applicant/hui: 2249 Kauai Rd. Koloa, HI 96756

Contact Phone: 808-742-9575 Email: terriehayes@gmail.com

Ahupua'a/ Moku: Mahaulepu Ahupua'a, Kona District

Check as many as applies to the issue you are reporting:

- Natural resource
- Cultural resource
- Traditional Hawaiian practice

1. Briefly describe the issue/ situation in which a resource(s) and/or traditional Hawaiian practice is affected:

If Hawaii Dairy Farms is allowed to import 699 cows to Mahaulepu Valley, the local Hawaiian people will be kept from collecting medicinal plants and waters from the valley. Once fences and cows arrive, Hawaiian fishing practices will be greatly impacted by 3 million lbs. of manure and 210,000 gallons of urine per month that will be deposited on the land and will runoff to the nearby sea (less than 1 mile away).

2. Describe the impact (negative) that will occur or is occurring to the environment or traditional Hawaiian practice as a result of the issue you are reporting:

The massive waste HOF cows will produce (>143 lbs/dog/cow) is to be left where it falls with no plan for removal. Direct runoff from the proposed farm site via the Waioapek stream has been confirmed. Cow manure has been shown to be an equivalent health risk to human sewage. Current swimming and fishing practices by Hawaiians will be greatly impacted.

3. Identify the ahupua'a, moku and/ or mokuuni residents impacted by the issue that you are reporting (in general): Native Hawaiian and local residents of Kona; Aha Moku Billy Kaohelaui'i, Kona District; and all the residents and visitors of the AHA'PUAA.

* For the purpose of establishing a common understanding to the term relevant to our directives as the 'Aha Moku Advisory Council, "Traditional Hawaiian practice" is identified as: a set of performance characteristics in a discipline, that has been maintained long enough to have become a custom, and has been practiced by indigenous Hawaiian people in a sequence of generations that precedes the modern Hawaiian era.

For Aha Moku Advisory Committee, DLNR, BLNR only

4. If applicable, describe the steps (if any) taken so far to try to resolve the issue: others have been sent to the Governor; the Director, both Director, Department of Land & Natural Resources; Board of Directors; and Management Personnel, Hawaii, Diving Teams / Ulukoupa Initiative; Mayor, County of Kauai; Board of Supervisors; The State County Council of Kauai and its Directors. The Planning & Public Works Department, expressing concern for the impact to traditional cultural practices.

5. Describe any practice in use presently that is consistent with (a) maintaining the health of the area affected and (b) maintaining established indigenous Hawaiian customs: At present, the area supports established agriculture including a taro farm. The limited development includes the taro farm which HDE is proposing to surround by cows, pasture, building, right up to the edge of the lot. The Makawahi Cave Preserve which is adjacent to the property is an extensive native Hawaiian plant restoration site. The area was also the subject of a National Parks Survey, proposing Hawaii Park restoration site. The area was also the subject of a National Parks Survey, proposing it as a National Park. A 50' x 100' site of subsistence fishing, gathering, hunting, length of time in practice.

Native cultural practices have extended back to the polynesian's first arrival w/ sacred spiritual importance following the defeat of King Kamehameha's army. The renewed us on saving/preserving endemic native species began about 15 years ago w/ the archeological excavations at the site of the Makawahi Cave Preserve which is adjacent to the property.

6. Please attach or note any data, evidence or support that can substantiate your position and provide assistance for the 'Aha Moku Advisory Council in determining appropriate follow-up procedures. Attachments include electronic transcripts of NRC's custom soil study (6/11/14), National Park Service (contingency survey) (2007), objection letters filed with the above (4/13 - present), public comment from Ahupua'a (2013), Kamehameha development plan report on the environment and sustainable pollution problem by the Independent Parliamentary Commission for the Environment (New Zealand 2013), and photos showing flow and potential erosion/shrubs under SHRP response to AIS (12/19/14)

7. Are there any residents of the identified area who have opposing views, contrasting management methods, or other interests? yes no

Please describe: The identified area is undeveloped and all nearby residents are opposed to the proposed industrial scale dairy. Through this complaint, the Ahupua'a Moku implies the State to act to prevent the certain environmental degradation and destruction of natural resources practices that will undoubtedly occur with the introduction of massive untreated animal waste.

If possible, can you suggest a compromise or alternative solution that you are willing to consider, that can help resolve the issue in a way that satisfies both parties' positions, in keeping with the principles of resource protection and traditional Hawaiian practices? THAT WOULD ACHIEVE RESOURCE PROTECTION AND PRESERVATION OF TRADITIONAL HAWAIIAN PRACTICES. REVOCATION TO ANOTHER SITE IS THE ONLY SUSTAINABLE COMPROMISE.

*The 'Aha Moku Advisory Council needs to know this information in order to fully assess the reported issue, determine whether or not the reported issue is consistent with our directives as an advisory council advocating traditional Hawaiian Resource management, and if so, to help us determine our recommendations to forward to the Department of Land and Natural Resources.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i

TMK: (4) 2-9-003:001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Hayes, Terrie and Kaohelauli'i, Billy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts,

retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project

property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive, if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top

of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kāua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure

application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be

dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search 'Hawai'i Dairy Farms': <http://hnyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: HI Dairy Farms EIS Preparation Notice
 Comments & Request to be a Consulted Party

Please allow me to introduce myself. My name is Suzanne Kashiwaeda and I am a retired social worker, single mother and still primary caregiver of an adult son with developmental disabilities. During my career as a social worker, I've worked with elderly individuals and groups, children with disabilities and their families, "at-risk" students, and families living in poverty conditions including homeless working families.

If you've ever had to provide 24/7 care to a person, you'd understand the critical need for respite to get away from the physical and emotional responsibilities, to recharge and renew your energy and spirit to continue to care for loved ones. Mahalepua is a place many of us go for solitude, solace and spiritual renewal.

Taking a holistic and longterm perspective, my concerns are many:

- An industrialized dairy operation of 2000 cows would alter the quiet, peaceful and pleasant ambience of Mahalepua and families and caregivers would lose this natural source for rejuvenation
- Runoff and pollution of nearby wells, aquifer, ocean and impact on reefs, coral, fish, other marine life can seriously and negatively impact both natural and economic resources.
- We are an island community and the time-honored Hawaiian concept of ahupua'a need to be seriously considered and health of reefs? Do roads, buildings and other infrastructure remain?
- Lava tubes can carry pollutants to the ocean. Can and will they be contributing to the pollution of Waikomo Stream and its ocean mouth? If Waikomo is polluted now, how much more will it be when millions of gallons of water are used a day as part of the operation of a 2000 cow dairy?
- If HDF follows in the footsteps of other Kauai dairies and ceases operations, what are plans for restoration of the land, pollution of ocean and health of reefs? Do roads, buildings and other infrastructure remain?
- There's a significant difference between industrialized agriculture and compatible and sustainable farming. Has a smaller dairy operation been considered? What monitoring criteria can be adhered to that would provide an indication of more appropriate carrying capacity and dairy size that does not negatively impact the land, ocean, and air quality.
- Aren't there any other farming options for this land that would be more compatible with this area?
- Aren't there any other more appropriate properties for an industrial sized dairy?

I understand from the meeting Group 70 held this past Thursday that individuals submitting comments will be 'consulted parties' and will receive notices, updated and pertinent information about this project. I look forward to learning more and trust that the EIS process will be thorough and objective.

Sincerely,
 Suzanne Kashiwaeda

Subject: Hawai'i Dairy Farms
 Environmental Impact Statement Preparation Notice
 Mahā'ulepū Road
 Kaula'i, Hawai'i
 TMK: (4) 2-9-003: 001 portion and 006 portion
 (4) 2-9-001:001 portion

Dear Suzanne Kashiwaeda:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Mahā'ulepū Valley on the island of Kaula'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex

were found. Such sites have been reported abng coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

COMMENTS re EIS on Hawaii Dairy Farms proposed for Mahaulepu, Kauai

To Whom it May Concern:

Please tell me that this is not a "done deal." Damage to nature cannot be healed in one's lifetime. There is so much conflict of interest involved in this process, I can't believe fairness can be achieved.

I think the "Head" of the Health Dept. should visit this area before making this decision.

Sincerely,
Delano

Dear Delano H. Kawahara:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Maha'ulepu Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP/N), published January 23, 2015, described the proposed pasture-based rotational grazing system

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility, surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of

Delano H. Kawahara

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

Subject: COMMENT re Hawaii Dairy Farms EIS Prep Notice
Date: Sunday, February 22, 2015 11:22:02 PM
Importance: High

To: Hawaii State Dept. of Health, Environmental Planning Office
919 Ala Moana Blvd., Rm. 312
Honolulu, HI 96814

To Whom it May Concern:

I have read through all regarding the proposed industrial dairy now under consideration for the Mahaulepu area of Kauai, my home island. Also, I attended the public meeting held at Koloa School's cafeteria on Thurs., Feb. 19, 2015, and visited all four corners of the Dairy Farms' displays, listening, looking, and reviewing questions over the din/hubbub (hard to hear).

My comment is that I am dead set against the use of this sensitive, beautiful and culturally significant piece of agricultural land adjacent to ocean and reef for the purpose as described. The bottom line as I see it is this: What is this dairy operation going to contribute to the Kauai community?

The milk is to be trucked/shipped off island; no milk, butter, cheese or yogurt is coming to us as a local product.

The next related question is: What is this dairy operation going to gain while taking and possibly ruining a highly prized part of our island?

I am sure the answer is in dollars, several figures. For the dairy as an agricultural corporate entity, and the CEOs and backer. And for Grove Farm Corp., the entity leasing the land. Any fool can see that this equation doesn't pan out: Kauai residents (not to mention visitors) gain nothing of value while allowing possible/probably ruination of land, sea and reef, and air quality. As in New Zealand, and recently in Minnesota and California, if an industrial dairy swings into operation on island, it's a given that sometime soon environmental protection laws will need to be passed to prevent illness and contamination —and aid in the healing and recovery of the people, land and water if possible. It will be slow process, since it's much easier to foul a place than return it to its earlier state. It's too great a risk to take.

Yet, in keeping the land in agriculture, as set forth in our zoning, it is highly possible to entertain thoughts of an ulu tree plantation, with hemp to begin a new fiber industry on island, and possibly free-range chickens naturally fertilizing within such farmlands. Foods of value, and fiber of value would be gained by Kauai residents with crops and poultry farming of this sort, which should be encouraged.

I say NO very definitely to the dairy proposal. I believe much of what has been presented to the public here by the dairy representatives is half-truth, or possibly more of a lie than truth.

Sincerely,
DAWN

Dear Dawn Fraser Kawahara:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

LAND USE: The historical and existing land uses of the project site and surrounding Māhā'ulepū Valley were examined in the Draft Environmental Impact Statement (EIS), and uses proposed by the Hawai'i Dairy Farms (HDF) project were evaluated in the context of county and state land use designations for the area. The evaluation of land use is presented in Draft EIS Chapter 4-4, and the project's consistency with government plans and policies is presented in Draft EIS Chapter 5.0.

The south shore of Kaua'i is home to some of the most productive farm land in the state, attributed to consistent sunshine, ample fresh water, and a large amount of Class A and B soils (with "A" representing the class of highest productivity soils and "E" representing the lowest). The large tracts of farmland, including those of Mahalepū Farm and Grove Farm, allow for stability in support of farm ventures,

help maintain regional water systems and provide agricultural employment for Kaula'i residents in addition to fresh, local food.

The project site is on agricultural land in Māhā'ulepū Valley, an area with a long history of agricultural use as it was the first place in the island chain where sugarcane was commercially grown. The site is in the Agricultural District per State Land Use District designations, and per the County of Kaula'i zoning ordinance. The site consists of land classified as Prime per the State Department of Agriculture's Agricultural Lands of Importance to the State of Hawai'i (ALISH). The HDF site is outside of the County-designated Special Management Area under the Coastal Zone Management Program.

In 2005, the State established Important Agricultural Lands (IAL) by statute. The purpose of IAL is to conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands. The designation process determines land meet physical requirements including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with high quality soil agricultural productivity ratings under the Land Study Bureau of University of Hawai'i.

In 2011, Mahaulepu Farm LLC filed a petition with the State of Hawai'i Land Use Commission to designate 1,533 acres of agricultural lands in Māhā'ulepū (including 557 acres that make up the HDF site) as IAL. IAL designation meets the objectives of the State HRS §205-42 by contributing to the maintenance of a strategic agricultural land resource base to support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities. See Figure 4.4-2 in DEIS Section 4.4.

The designation process determined that the land meets a number of physical requirements established in HRS §205-45, including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with 88.5 percent of the area featuring an overall soil agricultural productivity rating of "B", per criteria established by the Land Study Bureau of University of Hawai'i.

The development and long-term operation of HDF will be in full compliance with its agricultural State Land Use District designation, ALISH classifications, and County zoning. The dairy farm will embody the intent of the IAL designation per the Hawai'i State Constitution, by using these protected lands for the intended purpose of diversified agriculture, food production and agricultural self-sufficiency. HDF development of a dairy also supports the "secondary intent" for lands in the Agriculture land designation, to provide an opportunity for Kaula'i citizens to reside in an agricultural community. This is in contrast to the described "agricultural subdivisions" that have changed parts of Kaula'i intended for a rural landscape, with development as quasi-suburban landscapes dotted with residences on large lots.

Overall, the project provides long-term benefit and support of agricultural lands and industry through continued use in keeping with zoning and IAL designation. Long-

term operation of the dairy does not preclude the region for future protection in a coastal park at Māhā'ulepū.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plascch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaula'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaula'i.

The HDF project would contribute to diversification of Kaula'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaula'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaula'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaula'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the

committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii's Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios.

Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural bases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).

- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OFQC website at the following URL, search "Hawaii Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

To Whom It May Concern:

I have serious concerns about the building and operation of an industrial dairy on our south shore, in the delicate ecosystem of Māhāulepū.

Building and operating this dairy involves an **irrevocable commitment** to loss or destruction of our limited and unique ecosystems.

In particular, there is a real and proven concern that the proposed dairy will affect or is likely to the damage the south shore's environmentally sensitive areas such as flood plains, beach, erosion-prone areas, geologically hazardous land, estuary, fresh water and coastal waters.

The proposed dairy would also contaminate groundwater, detrimentally impacting the environment and public health. Large dairies in the United States have been found responsible for contamination of groundwater. Groundwater contamination is especially concerning for this project, as the aquifer in the area provides potable drinking water for the County of Kaua'i Department of Water Supply.

Please honestly and straight-forwardly address these concerns and many other concerns that are being raised by residents, aquatic biologists, environmental scientists and health professionals.

Sincerely,

Lani Kawahara

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Lani Kawahara:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawaii Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths –

Lani Kawahara
May 26, 2016
Page 2 of 6

as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaii Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of

groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waioipili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built

facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waioipili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waioipili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waioipili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waioipili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waioipili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waioipili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waioipili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to

create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the

Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

GROUP 70 INTL

Re: Hawaii Dairy Farms, Kauai

Comments to be considered in preparation of an Environmental Impact statement for:

Project Name: Hawai'i Dairy Farms

Island: Kaua'i

District: Poipu

TMK: (4) 2-9-003:001 (portion); 006 (portion)

(4) 2-9-001:001 (portion)

Aloha Ms. McIntyre:

After carefully reviewing the plan for the Hawaii Dairy Farm (HDF) provided to the public for comments to be considered in drafting the Environmental Impact Statement I would assert that HDF has caused serious environmental impacts during their grubbing and grading process prior to the arrival of cows and that upon arrival of the cows the impacts would be significant. HDF will not be able to mitigate the cumulative impacts HDF will have on the environment, public health and local businesses.

First and foremost HDF must prove that there will never be discharge of pollutants from direct surface runoff or ditch discharge into Waiopili stream, and that percolation into both shallow and deep groundwater will not contaminate stream, estuarine and near shore coastal waters. It would appear there are multiple areas and weather events that could cause possible breaches. Please identify all possible areas and weather events that could cause breaches. On the third page of the EISPN HDF uses the words "Grass-fed dairy". What are the USDA requirements for a dairy to call itself "grass-fed"? Why does HDF represent themselves to our community as being "grass-fed"? Does HDF meet the USDA standards to be called "grass-fed"?

How are the barns referred to in the EISPN going to be used? Please define and be specific as to what "several years" to establish the herd means.

What range do the nutrient readings need to be in to determine that it is not wise to bring another cow onto the site? What percentage of the paddocks will need to be in the correct range of the nutrient analysis to bring more cows? What percentage of the paddocks need to be in the detrimental range to halt the addition of cows? How often will the nutrient analysis be done on all of the paddocks? What will HDF do with their cows if the nutrient analysis doesn't support the number of cows they have?

What about the herd's health, why isn't that being used to determine if HDF has too many cows? For the health of the cows becomes a limiting factor, what are the standards and parameters HDF will use? (number of downer cows?)

How is HDF's plan any better than the NZ Model when it comes to the degradation of the water, air, and the environment? Please incorporate into the EIS the common breaches occurring in New Zealand on properties abutting or containing waterways so we can examine them in direct comparison to the HDF plan's impact.

How does the site being in the Flood Zone X impact the environment when looking at the weather hazards (hurricanes, tropical depressions and storms, etc.) that have occurred on our small island? If the soils are "supportive of nutritious grass types" as stated in the EISPN then why did the grass planted last spring fail to thrive?

What leads HDF to believe Grove Farms can supply them with 3 million gallons of water per day that they require to operate, when Grove Farms is not a utility company? The water belongs to the people of Hawaii under the state constitution (Public Trust Doctrine) have you asked the people if they want 3 million gallons of water per day diverted to HDF?

What will HDF do to get 3 million gallons of water per day when, as in Maui, the water is returned to its natural course?

What size bond is HDF putting up for cleanup when a natural disaster occurs? If there is no bond what is the rationale behind that when anyone that lives here knows it's a matter of when not if? What will be done to protect the cows during flash floods, tropical storms, tsunamis and hurricanes? What will be done to protect the cows from the extreme heat (over 90 degrees and up to 104 degrees per pg. 59 of HDF waste management plan) of the valley as there are no trees for them, only Norfolk pine trees to line the entry road?

The Waiopili stream originates from the HDF site via springs, ground water and, mountain runoff and goes to the ocean. It has the highest bacteria count of any stream on Kauai. The ocean has high reading in front of Gillian House where the stream is polluting the ocean. Older

readings by the Department of Health show that 2008 and 2010 readings for this area had were in acceptable range. What steps has HDF taken to keep soil from being washed into the stream during grubbing and grading? How will HDF clean up the stream before bringing cows?

What is HDF's expected total cost for all improvements? How much are the tax credits valued at for these improvements because of IAL designation of the property?

Where did you get your computations and information on the distances to populated areas? The Gillin house is much much closer as well as the Hyatt Resort and all of Poipu Kai homes and condos and Poipu Aina development of home sites and existing homes are less of a distance than Koloa town. What are the distances to the aforementioned properties from the closest corner of the HDF site not the effluent ponds? Please measure again these distances.

Please cite where you found the information that there were concerned citizens over the loss of Ag land that wanted Grove Farms site (HDF site) protected under IAL?

HDF states the quality of the land was studied during the designation process and was determined to be high quality soil? How is that?

Where is this study, who did the study and what are their qualifications? Why does that statement contradict 2014 NRCS soils report? The EISP states the most abundant soils are Kalihi and Ka'ena, brown variant, which the 2014 NRCS study states these soils have a very slow infiltration rate (high runoff potential), how can this be considered high quality soil?

If an invasive species is already on the island of Kauai, explain your thought process that more is better or alright to establish in respect to Kikuyu grass. How will the wetlands be protected from the invasive Kikuyu grass? The EISP sights Kikuyu-guinea grasses are to be used. One is a matting grass and the other a clumping grass, how are they not going to compete with one another? Kikuyu grass is toxic to cows if they eat it down past a certain point, how is HDF going to monitor the grass so the cows are sickened? Who are your horticultural experts and what are they saying in regards to the attempts that have been made to grow Kikuyu? Where are their reports as it would appear even to a layperson that the Kikuyu is suffering from failure to thrive?

The EISP states that DOH regulates waste management utilizing EPA's requirements. What are these requirements and how does HDF's plan meet or fall short on these requirements? The EISP states that in September and October 2014 a waste management

plan was reviewed by the DOH. Was the waste management plan approved of by DOH? If so please furnish the paperwork stating approval of the waste management plan. Doesn't the DOH refer to a dairy of 699 cows as a medium size CAFO? Isn't HDF a medium size CAFO?

Aren't the cow walkways sloped so water will runoff and not destroy the integrity of the walkway? What is the distance from the edge of the walkway to the closest edge of the reopened drainage ditches that are connected to the Waipili Stream? Will the manure and urine from the cows twice a day trek to the milking barn be cleaned up off the walkways that are sloped towards the reopened ditches? What precautions were taken during grubbing and grading to protect the ditches from soil runoff? What was done to protect the receiving waters of the Waipili Stream and ocean during the cleaning out and reopening of the ditches from soil erosion? Are the future plans for maintenance of the ditches the same as during grubbing and grading?

What will be done with the milk in the storage tank should the milks temperature reach above 45 degrees? How will this affect the ditches, the stream and the ocean? How many gallons of milk would this be if the storage tanks are completely filled?

Before HDF gets approved for their operating permit from DOH won't they need to get approval from DNLR?

Has HDF considered eliminating the settling pond and instead first removing all of the particulate from the wash down water, using a passive or automated incline screen followed by a continuous sand filter, like a Dynasand? If so why did you not explore this option as by using this process you would have a higher quality effluent to hold in the irrigation pond, making a flooding event considerably less damaging to the environment? For what reason would you not use a system that the solid waste would be dewatered at the source and easily used for composting or waste-to-energy? If this system was used with aeration of the pond then the odor would be minimized. Why would you not be a good neighbor and minimize the odor through this process? HDF talks about covering the effluent ponds when speaking with the community, why not commit? Who is the veterinarian for the cows? How often will he be checking the entire herd for health related issues, which are multiplied by the number of cows in close proximity to each other and standing in their own and other cows' manure that is left on the ground in the paddocks?

If you chose the CAFO alternative and used the Dynasand method then less water would be needed. Why not use less water?

Why not consider using smaller multiple sites for your cows, when considering alternatives, this would be more environmentally sound? Is it all about the money or is the environment worth spending more money to protect it?

What large land owners besides Grove Farms in the Hawaiian Islands have you contacted and taken a serious look at the feasibility of their sites? Would any of them be more protective of the environment? How many of the sites be more protective of the environment? If the sites were more protective, what was the rationale behind rejecting the sites?

Do you believe the Important Agricultural Land designation with all its tax benefits was intended to help small farmers succeed and not for large profitable corporations?

HDF states in the EISPN that initial operations are permitted to begin with up to 699 cows. Where is the operating permit? Could you make a copy available to the community?

What access will the community be allowed to the cultural sites? How are these sites to be protected from the effects of acid rain that is produced when hydrogen sulfide produced by the cows meets with rain?

How often does the temperature in the valley exceed 86 degrees?

What are the highest of the temperatures that exceed 86 degrees?

How will the cows be protected during this extreme heat?

How many times has the rainfall exceeded 50" per annum? When

was the longest and most extended rainfall event recorded on Kauai? What major events happened during this time? How would this effect soil erosion in the valley? Where will the cows go during such events? How will they be protected?

The EISPN states no known seismic activity has originated among these northern islands then why does the earthquake map from USGS, Atlas of Natural Hazards in the Hawaiian Coastal Zone show one on their map in Maha'ulepu area?

There are new flood maps, what was the date of the flood map that was cited in the EISPN?

The EISPN states that during hurricanes, operational plans for safekeeping of the dairy's livestock will be identified in the Draft EIS.

What about the enormous quantity of manure on the ground, how will that be protected from leaving the dairy during a hurricane that comes with torrential rains?

The EISPN states the average annual rainfall in Maha'ulepu is 50" why is this figure so different than the 60" to 100" mean annual precipitation cited in the 2014 NRCS Soils report? The change in number of inches of rain due to climate change needs to be accounted for in the EIS draft.

How far away is Koloa drinking water well F from the proposed desludge site, block H at its closest point? What is the ability of the soil to transport water/liquids in Block H? How long would it take for the liquids from the desludge to migrate through this type of soil after a rain storm?

What are the readings from the baseline air quality test? If HDF hasn't done a current air quality study before any cows come, why not?

What are the noise readings from HDF baseline study? If HDF hasn't done a baseline study, why not?

How many decimals is the bawling of a new mother cow when separated from her calf? How many decimals higher in terms of human hearing is the bawling at night when ambient sounds

disappear? Based on HDF's plan approximately 333 cows will be separated from their new born calves every two months. What is the decimal reading of 333 cows bawling after being separated from their calves? How many days on average do mother cows bawl for their calves and how many hours per day on those days? What is the EPA permissible noise level in a populated community? How does the EPA level compare to the noise level of cows bawling?

Will HDF have an air monitoring system on location? What type of system? How is it calibrated for accuracy? Who will be responsible for recording the readings and alerting the community and officials when it surpasses Hawaii's or EPA standards, will it be an unbiased person or an HDF employee? How often will the reading be reported to the community so as to alert community members with

respiratory problems? What are the readings on the six pollutants for air quality established by EPA (NAAQS) that should not be exceeded? What will HDF do to resolve the problem of poor air quality if it should occur for each of the six pollutants? How will the farm workers be protected from air pollutants seeing as they would get the brunt of the pollution? What kind of health insurance will be provided for the workers?

In regards to your irrigation system. What is the dimensions of the 2 pivots circles- radius etc.? How many wheel assemblies are there and what is the tonnage load per wheel section both empty and full? How are the certain ruts treated? What is the total mileage of the

individual wheel section tracks? What are the specs re: slope climbing ability of the HDF pivot system? Where is it emptied out when transitioning between effluent spreading and irrigation use? What is the uniformity/spread certainty, error rate distance of the end gun system that HDF proposes? Rutting is a common problem with wheels/booms getting stuck. Will this create an over application of effluent? How is HDF going to deal with wheel rutting problems causing new ditches in which the water/effluent can flow into the stream?

The plan states that disludging "hydrants which have a "gun sprinkler" with a 5/8 inch nozzle attached via a length of flexible hose", does this meet code?

What is the exact amount of water usage per dairy cow per pre-milking wash down?

The plan that West Kauai Soil and Water Conservation approved in 2013 is no longer as that plan was unacceptable to DOH and a complete new plan(July 2014) has been adopted by HDF. When is HDF going to submit the new plan for approval to the West Kauai Soil and Water Conservation?

What is the depth to Water Table for the soil (kavc) pod 159 of the burial pits? Are you planning on leaving 2 feet of soil above the water table before HDF buries a cow? Are you planning on spacing the dead cows 2 feet apart horizontally? HDF's archaeologist said at the Feb 19th, 2014 meeting that the water table was at 3.5 feet deep. If you need to leave 2 feet above the water table that would only leave 18 inches. How wide are dead cows? What are your

calculations on how many dead cows you can bury in your cemetery? Where is HDF going to put them after the cemetery is full? Will the cemetery seep deteriorated matter to the nearby wetland on the property next door? What steps will be taken to stop possible seepage? Should there be seepage how would this impact the endangered and water birds? How is HDF going to stop the large rain runoff from coming down the mountain and floating up the dead cows?

Where is the large depression referred to in the Kaaui Reconnaissance Survey? What is being done to protect it? How will the Makuawahi cave that floods every couple of years, be protected from contaminated runoff from the HDF site? This contamination would include manure, urine, fertilizers, antibiotics, hormones and phosphorous and nitrates.

How is HDF going to protect the community from being bit by the biting flies while trying to enjoy the beach? How is HDF going to

protect the community at large from biting flies? Will HDF be responsible for all medical bills, pain and suffering inflicted by the biting flies as a vector for disease?

Have you studied the diseases caused by flies as a vector? Why not? Are you going to make the study available to the community at large? What is HDF going to do to protect the wetlands and nesting environments from becoming inundated with the invasive kikuyu grass causing the endangered species loss of their forage?

What will be done to protect the waterbirds, the Newell Shearwater, the migratory birds, the indigenous species, the terrestrial invertebrates, the marine vertebrates, the reef fish, the arthropods and the seaweed that the local people gather? Please address these individually citing their habitat needs and how those are being protected? What will be done in the event of a breach to insure that these species are not desecrated?

The social-economic impacts will be greatly significant. How much will house values drop within 5 miles of the dairy? Please denote these figures for every half mile increment. How far can flies travel? Once a fly reaches another moist area, how far will it fly from there? How many larvae does each fly lay? What is the exponential number of flies after a year of the dairy opening if we start with one fly per cow (2,000 flies)? How will this affect homes with pools value within 5 miles of the dairy? How far will the odor travel based on an average day's northeasterly or easterly wind speed of between 15-17mph? How will HDF protect the community including Keiki and Kapuna from the gases and particulate produced in the air by the dairy? What about the community members that have compromised lungs? Will HDF pay for their medical expenses if their conditions take a turn for the worst after the dairy is in? Many dairies purchase the homes that are impacted by their operations, how many will HDF purchase?

The EIS must study the impacts to the environment and study the potential impacts to the Poipu visitor economy which will be significantly impacted by the environmental consequences of such an intensive land use in the Maha'ulepu valley. How many jobs would be lost at the Hyatt because of odor and flies? Does HDF plan on remunerating the Hyatt for lost business? What about the owners at Poipu Kai and other vacation rentals loss income?

What will HDF do to address the impact of acid rain created by the off gassing of their cows?

Will HDF be paying the county to accept their solid waste? What is the county's cost per ton for their HDF? How much will HDF pay per ton?

The EISPN states that the site has a system of ditches to channel storm water through the area, as well as to drain fields. Are these the same fields where the manure and urine are left on the ground? Would this not be considered nonpoint source discharge? Wikipedia defines nonpoint source discharge as, "Nonpoint source (NPS) pollution refers to both water and air pollution from diffuse sources. Nonpoint source water pollution affects a water body from sources such as polluted runoff from agricultural areas draining into a river, or wind-borne debris blowing out to sea." Specifically how is HDF's operation any different than as defined nonpoint source discharge?

I hereby incorporate all of the questions and/or concerns voiced by the community at the Feb 19, 2014 meeting at Koloa Cafeteria that HDF and Group 70 put on for the community.

Please respond to the above questions in your draft EIS as they speak to several of my concerns over Hawaii Dairy Farms operation and their choice of locating their dairy in an environmentally sensitive area.

I wish to be a party to this EIS and receive any and all notifications and emails.

ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE

An Environmental Impact Statement (EIS) is being prepared voluntarily by the Applicant to assess potential environmental impacts and mitigation measures associated with agricultural operations at Hawai'i Dairy Farms (HDF) at Maha'ulepu, Kauai.

To assist in preparing the EIS, an Environmental Impact Statement Preparation Notice (EISPN) was recently published. A 30-day public comment period on the EISPN ends February 23, 2015. The purposes of the publication and comment period are two-fold:

1. to allow individuals and groups to request to become a consulted party; and
2. to provide written comment regarding effects of the proposed action.

NOTE: Submitted comments will be published in the Draft EIS

COMMENT

Name: Eileen Kechloian Organization: _____

Preferred contact Method

Email: backomisland@gmail.com Postal Address: 1722 Keoniloa Pl Koloa

Phone: (Optional) 96756

Comments: HDF Says they are a Zero-discharge does they mean they are also a nonpoint source discharge? Does zero-discharge mean only from effluent pond? What about the manure left on the ground? Why did you wait until the 19th of Feb to have a meeting for the community when all the comments must be post/mark Feb 3rd? Why did you think that Friday to Monday was enough time for those who need help writing? Why did you not have an opening prayer when it was requested as it a culturally appropriate practice? Why did you choose a venue that was too small to accommodate the people who stood outside?

Subject: Hawaii Dairy Farms
Environmental Impact Statement Preparation Notice
Mahā'ulepū Road
Kaua'i, Hawaii
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Eileen Kechloian:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Mahā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPEN), published January 23, 2015, described the proposed pasture-based rotational grazing system

Eileen Kechloian
May 26, 2016
Page 2 of 22

as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPEN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Mahā'ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways

and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of

699 mature dairy cows at the Māhā'ulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai'i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

CLIMATE: Draft Environmental Impact Statement (EIS) Section 4.1 addresses climate conditions. Climatic conditions affect the growth of forage and the health of dairy cows. Heat stress can reduce the productivity of dairy cows, and suitable climatic conditions were an important consideration in siting the dairy.

The Po'ipū area is generally known for its mild conditions. The area's climate is greatly influenced by its inland location and valley topography. Winds in the Po'ipū area are generally from the east-northeast direction (tradewinds) ranging from 5 to 15 miles per hour. Wind conditions vary depending on season and weather conditions, as occasional storms can generate strong Kona winds from the south, and land breeze circulations can develop during times of weak tradewind conditions. Meteorological data for 2014 was obtained for the project site. The predominant winds from the northeast, and the strongest winds come periodically from the southwest.

Rain gauge data for a rain gauge located near the site off Māhā'ulepū Road was obtained from NOAA National Climatic Data Center. The data reveal that more than a week of consecutive rain is very unusual for Māhā'ulepū Valley. The rainfall events for 30 years were recorded (a total of 10,957 days from 1984 to 2013) and ranked based on days of consecutive rainfall (DAPR) and the corresponding multi-day precipitation total (MDPR). Data records show only five occurrences in the last 30 years with more than a week of consecutive rain. And rainfall exceeded 2.0 or more inches during only four occurrences, with 2.6 and 3.7 inches recorded (EIS Section 4.1). Average rainfall in Māhā'ulepū is just under 50 inches annually.

Changes to solar radiation and the hydrologic cycle large enough to affect climate would be large-scale and long-term. The scale of HDF is not large enough to influence global cycles of solar radiation and the hydrologic cycle. Minimal construction and an increase in ground cover density will not affect climate

processes. The 557-acre site is not large enough to have a regional influence on climate.

Annual rainfall, prevailing winds, and solar radiation conditions at the HDF site are well suited to growing dairy pasture grass and conducting pasture-based dairy operations. Neither the committed herd size of 699 mature dairy cows nor the contemplated herd size of up to 2,000 mature dairy cows will affect climate conditions over the short-term or long-term. No significant impacts are anticipated, and no mitigation would be required.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaching fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West-Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawaii." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Luualalei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate

that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunamis, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhalepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside

the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-

Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonex were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā'ulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai'i's endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its

present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened

invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *Drosophila musaphilia*, the only Kaua'i species of native Hawaiian fly listed as Endangered or Threatened. Native *Drosophila* habitat is located many miles away in the high elevation koa-ōhī'a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai'i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua'i and those species already in Māhā'ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Poi'ū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Kūnoiki Road between Kōloa and Poi'ū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals' wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

NOISE: Existing noise conditions of the project site and the surrounding Māhā'ulepū valley area are evaluated in the Draft Environmental Impact Statement (EIS), along with anticipated short-term and long-term noise conditions associated with the

dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai'i Department of Health (DOH) rules use the A-weighting sound network (dBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes. The Hawai'i Dairy Farms (HDF) site in Māhā'uiept Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition, occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 78 decibels or that cost a total of more than \$250,000. Mitigation measures to minimize construction noise will include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plach Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include

equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately \$68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at \$160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately \$8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows (\$76,000 total versus \$68,000 for the committed herd size). The State will derive approximately \$360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking

parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua'i will increase county-wide by 17,300 residents by 2030. The South Kaua'i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua'i region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island's infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface

Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the Indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (<http://health.hawaii.gov/cwb/>).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent, Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the *Clean Air Act of 1970* (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of

air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own *State Ambient Air Quality Standards* (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM_{2.5}) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 µg/m³, well below the State standard of 150 µg/m³. The estimated concentration for PM_{2.5} is 0.23 µg/m³, well below the Federal standard of 35 µg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were

applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of the panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land

uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural bases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.

- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": <http://tinyurl.com/OEQCKAUAI>

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.
